Statement Regarding Generative AI

No part of this thesis had been aided by generative AI.

Acknowledgements

I thank my advisor, Professor Maksym Radziwiłł, for his guidance on topic selection, explanation of current literature, and insights into solving hybrid Guth-Maynard.

Chapter 0

Notation and Preliminaries

Notation

We denote summation over the natural numbers \mathbb{N} to be over the positive integers. We always denote p as a prime, and by extension p_j, p_n etc. We denote $e(x) := \exp(2\pi ix)$. For asymptotic behaviors, we write $A \ll B$ if there is an absolute constant c such that $A < cB$, and $A \ll_\epsilon B$ if $A < cB$ with c possibly depending on ϵ . Similar to the notation in Guth-Maynard's paper, we write $A \asymp B$ if $A \ll B$ and $B \ll A$ and $A \sim B$ for $B < A \leq 2B$. We also write $A \lesssim B$ if $A \ll_\epsilon T^\epsilon B$ for any $\epsilon > 0$. Words on top of a relation denote the theorem applied to derive the relation, for instance $\stackrel{\text{Poisson}}{=}$ and $\stackrel{\text{CS}}{\leq}$ means that Poisson summation and Cauchy-Schwarz is applied respectively.

Preliminaries

Here we provide some supplementary definitions and statements of theorems. These results are well-known.

Number Theory

Definition 0.1 (Dirichlet Characters). *Let $q \in \mathbb{N}$. A Dirichlet character $\chi : \mathbb{N} \rightarrow \mathbb{C}$ modulus q is an arithmetic function satisfying*

- (Periodicity) $\chi(n + q) = \chi(n) \forall n \in \mathbb{N}$.
- (Complete multiplicativity) $\chi(nm) = \chi(n)\chi(m) \forall n, m \in \mathbb{N}$.
- $|\chi(n)| = \begin{cases} 1, & \text{if } \gcd(n, q) = 1, \\ 0, & \text{otherwise.} \end{cases}$

Proposition 0.2. *There are $\phi(q)$ Dirichlet characters of modulus q .*

Proof. Taking residual classes mod q , we see that Dirichlet characters are in one-to-one correspondence with one-dimensional representations of the multiplicative group $(\mathbb{Z}/q\mathbb{Z})^\times$. Since this group is abelian, all of its irreducible representations are one-dimensional. Therefore, the number of Dirichlet characters equals the number of irreducible representations of the $(\mathbb{Z}/q\mathbb{Z})^\times$. It is known that the sum of squares of the dimensions irreducible representations equals the order of the group, so we have

$$\phi(q) = |(\mathbb{Z}/q\mathbb{Z})^\times| = \sum_{\text{irreducible representations } \varphi} (\dim \varphi)^2 = \sum_{\text{irreducible representations } \varphi} 1.$$

□

Definition 0.3. A Dirichlet character χ modulus q is induced by another character χ^* mod $m < q$ if they agree on all n such that $\gcd(q, n) = 1$. A Dirichlet character is primitive if it is not induced by another character. A Dirichlet character is principal if it is induced by the character $\chi_1(n) := 1(n) \equiv 1$, thus corresponds to the trivial representation.

Theorem 0.4 (Möbius Inversion). The Möbius function μ is defined for $n \in \mathbb{N}$,

$$\mu(n) = \begin{cases} 1, & \text{if } n = 1 \\ (-1)^k, & \text{if } n = p_1 p_2 \dots p_k \text{ for distinct } p\text{'s} \\ 0, & \text{otherwise} \end{cases}$$

Suppose we have arithmetic functions f, g , and that

$$f(n) = \sum_{d|n} g(d)$$

Then the Möbius Inversion formula gives

$$g(n) = \sum_{d|n} \mu(d) f\left(\frac{n}{d}\right)$$

Example 0.5. On $\Re(s) > 1$, let $M_N(s) = \sum_{n \leq N} \mu(n) n^{-s}$. Then setting $f(n) = 1$ for all n , $g(1) = 1$, $g(n) = 0$ for $n \geq 2$, we multiply M_N by ζ in Dirichlet series to get

$$\zeta(s) M_N(s) = \sum_n \frac{a_n}{n^{-s}},$$

where $a_n = g(n)$ for all $n \leq N$. Similarly, letting $M_N(s) = \sum_{n \leq N} \chi(n) \mu(n) n^{-s}$ for some Dirichlet character χ , we get

$$L(s, \chi) M_N(s) = \sum_n \frac{a_n \chi(n)}{n^{-s}}$$

with the same a_n as in the previous equation.

Harmonic Analysis

Theorem 0.6 (Fourier Inversion). In Schwartz space, the Fourier transform of $\mathcal{F} : \mathcal{S}(\mathbb{R}^d) \rightarrow \mathcal{S}(\mathbb{R}^d)$ of $f \in \mathcal{S}(\mathbb{R}^d)$ is given by

$$\hat{f}(\xi) := \mathcal{F}f(\xi) := \int_{\mathbb{R}^d} e(-\xi \cdot \mathbf{x}) f(\mathbf{x}) \, d\mathbf{x}$$

has inverse given by

$$f(\mathbf{x}) = \mathcal{F}^{-1} \hat{f}(\mathbf{x}) := \int_{\mathbb{R}^d} e(\xi \cdot \mathbf{x}) \hat{f}(\xi) \, d\xi.$$

Theorem 0.7 (Mellin Inversion). The Mellin transform of a function $f : (0, \infty) \rightarrow \mathbb{C}$

$$\tilde{f}(s) := \mathcal{M}f(s) := \int_0^\infty f(x) x^{s-1} \, dx$$

has inverse

$$\mathcal{M}^{-1} \tilde{f}(x) = \int_{c-i\infty}^{c+i\infty} \tilde{f}(s) x^{-s} \, ds$$

on $a < c < b$ provided that the integral \tilde{f} is absolute convergent on the strip $a < \Re(s) < b$.

Theorem 0.8 (Poisson Summation). Let $f : \mathbb{R} \rightarrow \mathbb{C}$ be Schwartz. Then

$$\sum_{n \in \mathbb{Z}} f(n) = \sum_{\xi \in \mathbb{Z}} \hat{f}(\xi).$$

Chapter 1

The Riemann Zeta Function and the Prime Number Theorem

1.1 Introduction to the Riemann Zeta Function

We give a quick introduction to the zeta function in this section, including its product representation and analytic continuation.

Definition 1.1 (Zeta Function). *Let $s \in \mathbb{C}$ with $\Re(s) > 1$. Then*

$$\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}. \quad (1.1)$$

The zeta function converges absolutely on $\Re(s) > 1$ by comparing to the integral $\int x^{-\Re(s)} dx$. The properties of the zeta function as they relate to the distribution primes. In particular, the Dirichlet series can be represented as a product of primes.

Proposition 1.2. *On $\Re(s) > 1$,*

$$\zeta(s) = \prod_{p \in \mathbb{N}} \left(1 - \frac{1}{p^s}\right)^{-1}. \quad (1.2)$$

Remark: This expression also converges absolutely for $\Re(s) > 1$. Since

$$\left(1 - \frac{1}{p^s}\right)^{-1} = \frac{p^s}{p^s - 1} = 1 + \frac{1}{p^s - 1}$$

and $\sum (p^s - 1)^{-1}$ converges absolutely by comparison to the zeta function Dirichlet series.

Sketch of proof. Write $s = \sigma + it$. For each p ,

$$\left(1 - \frac{1}{p^s}\right)^{-1} = \left(\frac{1}{p^s} + \frac{1}{p^{2s}} + \frac{1}{p^{3s}} + \dots\right)$$

converges absolutely for $\Re(s) > 1$ and uniformly across all p . We thus take for $m > N$

$$\begin{aligned} \prod_{p \leq N} \left(1 - \frac{1}{p^s}\right)^{-1} &= \prod_{p \leq N} \left(\sum_{k=1}^m \frac{1}{p^{ks}} + O(2^{-m\sigma})\right) \\ &\stackrel{(*)}{=} \sum_{n=1}^N \frac{1}{n^s} + O_1\left(\sum_{n=N+1}^{\infty} \frac{1}{n^{\sigma}}\right) + O(2^{-m\sigma}) \\ &= \zeta(s) + O_1\left(\sum_{n=N+1}^{\infty} \frac{1}{n^{\sigma}}\right) + O(2^{-m\sigma}) \end{aligned}$$

Where we apply to Fundamental Theorem of Arithmetic in (*) to show that each term n^{-s} has coefficient 1 determined by the unique prime factorization. As $m \rightarrow \infty$, $2^{-m\sigma} \rightarrow 0$. Then we take $N \rightarrow \infty$, the tail of the infinite sum converges to zero too. \square

Proposition 1.3. ζ extends to a meromorphic function on \mathbb{C} with a simple pole at $s = 1$. By abuse of notation, we identify the extension of the zeta function with ζ too.

We will prove Proposition 1.3 in two steps. First, we will extend ζ to $\sigma > 0$. Then, we will describe the continuation of the zeta function to the whole plane using by its functional equation: ζ has a line of symmetry across $\Re(s) = 1/2$.

Proposition 1.4. Let $\xi(s) := \pi^{-s/2} \Gamma(s/2) \zeta(s)$. Then

$$\xi(s) = \xi(1-s). \quad (1.3)$$

Extension of ζ to $\sigma > 0$. We apply integration by parts on Dirichlet series when $\sigma > 1$

$$\begin{aligned} \zeta(s) &= \int_{1/2}^{\infty} x^{-s} d[x] \\ &= s \int_{1/2}^{\infty} [x] x^{-s-1} dx \\ &= s \int_1^{\infty} x^{-s} - \frac{\{x\}}{x^{s-1}} dx \\ &= \frac{s}{s-1} - s \int_1^{\infty} \frac{\{x\}}{x^{s-1}} dx \end{aligned}$$

where in the last expression, the integral converges when $\sigma > 0$, and the pole at $s = 1$ arises from the first term. \square

Proof of Proposition 1.4. Using

$$\Gamma(s) = \int_0^{\infty} e^{-x} x^{s-1} dx,$$

we make the substitution $x = \pi n^2 y$ to get

$$\begin{aligned} \Gamma(s) &= \int_0^{\infty} e^{-\pi n^2 y} (\pi n^2 y)^{s-1} \pi n^2 dy \\ \implies \frac{\Gamma(s)}{\pi^s n^{2s}} &= \int_0^{\infty} e^{-\pi n^2 y} y^{s-1} dy \end{aligned}$$

So that by the Monotone Convergence Theorem,

$$\begin{aligned} \pi^{-s/2} \Gamma(s/2) \zeta(s) &= \sum_{n=1}^{\infty} \frac{\Gamma(s/2)}{\pi^{s/2} n^s} \\ &= \sum_{n=1}^{\infty} \int_0^{\infty} e^{-\pi n^2 x} x^{s/2-1} dx \\ &= \int_0^{\infty} \sum_{n=1}^{\infty} (e^{-\pi n^2 x}) x^{s/2-1} dx. \end{aligned}$$

We now let

$$\omega(x) = \sum_{n=1}^{\infty} e^{-\pi n^2 x}, \quad \theta(x) = \sum_{n=-\infty}^{\infty} e^{-\pi n^2 x} = 2\omega(x) + 1,$$

and apply Poisson Summation to

$$\theta(x) = \sum_{n=-\infty}^{\infty} e^{-\pi n^2 x}$$

$$\begin{aligned}
&= \sum_{k=-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-\pi y^2 x} e^{-2\pi i k y} dy \\
&= \sum_{k=-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-\pi y^2 x} e^{-2\pi i k y} dy \\
&= \sum_{k=-\infty}^{\infty} \frac{1}{\sqrt{x}} \int_{-\infty}^{\infty} e^{-\pi u^2} e^{-2\pi i k u / \sqrt{x}} du \\
&= \sum_{k=-\infty}^{\infty} \frac{1}{\sqrt{x}} e^{-\pi k^2 / x} \\
&= \frac{1}{\sqrt{x}} \theta\left(\frac{1}{x}\right)
\end{aligned}$$

using the substitution $y\sqrt{x} = u$. Replacing with ω ,

$$\sqrt{x}(2\omega(x) + 1) = 2\omega\left(\frac{1}{x}\right) + 1 \implies \omega\left(\frac{1}{x}\right) = \sqrt{x}\omega(x) + \frac{\sqrt{x}}{2} - \frac{1}{2}.$$

We thus write, using $y = 1/x$,

$$\begin{aligned}
\xi(s) &= \int_0^1 \omega(x) x^{s/2-1} dx + \int_1^\infty \omega(x) x^{s/2-1} dx \\
&= \int_1^\infty \omega(1/y) y^{-s/2-1} dy + \int_1^\infty \omega(x) x^{s/2-1} dx \\
&= \int_1^\infty \left(\sqrt{y}\omega(y) + \frac{\sqrt{y}}{2} - \frac{1}{2} \right) y^{-s/2-1} dy + \int_1^\infty \omega(x) x^{s/2-1} dx \\
&= \int_1^\infty \left(\frac{\sqrt{y}}{2} - \frac{1}{2} \right) y^{-s/2-1} dy + \int_1^\infty \omega(x) (x^{s/2-1} + x^{-s/2-1/2}) dx \\
&= \frac{1}{1-s} + \frac{1}{s} + \int_1^\infty \omega(x) (x^{s/2-1} + x^{-s/2-1/2}) dx \\
&= \frac{1}{s(1-s)} + \int_1^\infty \omega(x) (x^{s/2-1} + x^{-s/2-1/2}) dx.
\end{aligned}$$

ω decays exponentially in x , so the integral converges and the last expression is well defined on \mathbb{C} with simple poles at $s = 1$ or $s = 0$. Finally, notice that the last expression is symmetric when s is replaced with $(1-s)$, so proves equation 1.3. \square

Finally, we extend to $\zeta(0)$ by noticing that the poles of the functional equation from $\zeta(1)$ and $\Gamma(0)$ cancel out, so the Riemann Extension Theorem can be applied.

From the functional equation, we get ‘trivial’ zeros of the zeta function from the poles of Γ .

Corollary 1.5. *On $\Re(s) > 1$ or $\Re(s) < 0$, $\zeta(s) \neq 0$, except $\forall n \in \mathbb{N}, \zeta(-2n) = 0$.*

Proof. Using the product representation of ζ where it converges, none of $(1 - p^{-s})^{-1} = 0$, so $\zeta(s) \neq 0$ on $\Re(s) > 1$. Γ has no zeros and has a simple pole at $-n$ for all $n \in \mathbb{N}$, so by equation 1.3 we get the zeros for $\Re(s) > 0$ are exactly at the negative even integers. \square

These zeros are known as the trivial zeros of ζ . The remaining zeros lie between $0 \leq \Re(s) \leq 1$.

Definition 1.6 (Critical Strip and Critical Line). *We denote the region $0 \leq \Re(s) \leq 1$ as the **critical strip**. We denote the line $\Re(s) = 1/2$ as the **critical line**.*

Corollary 1.7. *On the critical strip, if $\zeta(s) = 0$, $\zeta(\bar{s}) = \zeta(1-s) = \zeta(1-\bar{s}) = 0$.*

Proof. This follows from equation 1.3, and $\zeta(\bar{s}) = \overline{\zeta(s)}$ holds where the Dirichlet series converges, thus holds everywhere. \square

The number of zeros in the critical strip can be calculated using the argument principle applied to the function ξ over the box with corners $-1 + iT, -1 - iT, 2 - iT, 2 + iT$. Applying the functional equation, we get the following result.

Theorem 1.8 (Number of zeros of ζ). *The number of zeros up to height T*

$$\#\{\sigma + it \mid \zeta(\sigma + it) = 0, 0 \leq \sigma \leq 1, |t| \leq T\} = \frac{T}{2\pi} \log \frac{T}{2\pi e} + O(\log T).$$

Theorem 1.8 is obtained by Riemann in his famous 1859 paper on the Zeta function, where he analytically continued the Zeta function and conjectured that all the zeros lie on the critical line [8].

Conjecture 1.9 (Riemann Hypothesis). *The **Riemann Hypothesis** (RH) asserts that on the critical strip,*

$$\zeta(s) = 0 \implies \Re(s) = \frac{1}{2}.$$

In section 2, we will use prove the Prime Number Theorem to demonstrate the connection of Zeta zeros and primes, with the Riemann Hypothesis leading to the tightest bound on the error term of the Prime Number Theorem. The Riemann Hypothesis has not be proved or disproved. Nevertheless, we can still obtain unconditional results on the error term through using the zero density of the Zeta function on the critical strip instead. This will be the main focus of section 3. We will provide a bound on the density of zeros in section 4 and refine it in section 5. Finally, extending from the ideas of the proof in section 5, we provide a generalization for the analogous zero density for Dirichlet L-functions.

1.2 The Prime Number Theorem

Theorem 1.10 (Prime Number Theorem). *Let $\Pi(N) = \sum_{p \leq N} 1$. Then*

$$\Pi(N) = (1 + o(1)) \frac{N}{\log N}.$$

In this section we will prove the Prime Number Theorem. This result is a minor goal of this paper. The Prime Number theorem serves as a starting point for studying primes in short intervals, and sets the stage for zero-density theorems.

Definition 1.11 (Von Mangoldt Function). *The **Von Mangoldt function** Λ is defined as follows:*

$$\Lambda(n) = \begin{cases} \log p, & \text{if } n = p^k \text{ for some } k \in \mathbb{N} \\ 0, & \text{else} \end{cases}$$

The sum of the Von Mangoldt function $\sum \Lambda(n)$ is a more natural way to express a prime counting function in the language of ζ . To see why, consider the expression

$$\begin{aligned} \frac{\zeta'(s)}{\zeta(s)} &= (\log \zeta(s))' \\ &= \left[- \sum_p \log(1 - p^{-s}) \right]' \\ &= - \sum_p \frac{p^s \log p}{1 - p^{-s}} \\ &= - \sum_p \log p \sum_{k \in \mathbb{N}} p^{-ks} \\ &= - \sum_{n \in \mathbb{N}} \frac{\Lambda(n)}{n^s} \end{aligned}$$

on $\Re(s) > 1$ where the sum and products are absolutely convergent.

Proposition 1.12. $\sum_{n \leq N} \Lambda(n) = (1 + o(1))N$ implies the Prime Number Theorem.

Proof. On one hand, we have

$$\begin{aligned} \sum_{n \leq N} \Lambda(n) &\leq \sum_{p \leq N} \Lambda(p) \\ &\leq \Pi(N) \log N. \end{aligned}$$

And for $\epsilon > 0$,

$$\begin{aligned} \sum_{n \leq N} \Lambda(n) &\geq \sum_{N^{1-\epsilon} \leq n \leq N} \Lambda(n) \\ &\geq \sum_{N^{1-\epsilon} \leq p \leq N} (1 - \epsilon) \log(N) \\ &= (1 - \epsilon)(\Pi(N) \log(N) + O(N^{1-\epsilon} \log N)). \end{aligned}$$

□

Moreover, the sum of the Von Mangoldt function can be related to the zeros of the zeta function. Let ϕ be smooth and rapidly decaying at infinity, and $\tilde{\phi}$ be its Mellin transform. Let $N \in \mathbb{N}$ and $c \geq 2$. Then

$$\begin{aligned} \sum_{n \in \mathbb{N}} \Lambda(n) \phi\left(\frac{n}{N}\right) &= \sum_{n \in \mathbb{N}} \Lambda(n) \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \tilde{\phi}(s) \left(\frac{n}{N}\right)^{-s} ds \\ &= \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \tilde{\phi}(s) \sum_{n \in \mathbb{N}} \Lambda(n) \left(\frac{n}{N}\right)^{-s} ds \\ &= \frac{-1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \tilde{\phi}(s) N^s \frac{\zeta'(s)}{\zeta(s)} ds \end{aligned} \tag{1.4}$$

By the rapid decay of $\tilde{\phi}$, we change the line of integration from c to $-\infty$, we get residue contributions from a pole at $s = 1$, $s = 0$, as well as all ρ such that $\zeta(\rho) = 0$ on the critical strip, and all the trivial zeros. Morally, we can take the indicator function $\phi = 1$ on $[0, 1]$.

$$\sum_{n \leq N} \Lambda(n) = \frac{-1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \frac{1}{s} N^s \frac{\zeta'(s)}{\zeta(s)} ds \tag{1.5}$$

If we move the line of integration across to $-\infty$, this gives

$$\begin{aligned} \sum_{n \leq N} \Lambda(n) &= N - \sum_{\rho} \frac{N^{\rho}}{\rho} - \frac{\zeta'(0)}{\zeta(0)} + \sum_{k \in \mathbb{N}} \frac{N^{-2k}}{2k} \\ &= N - \sum_{\rho} \frac{N^{\rho}}{\rho} - \frac{\zeta'(0)}{\zeta(0)} + \frac{1}{2} \log(1 - N^{-2}). \end{aligned} \tag{1.6}$$

This formula, due to von Mangoldt, can be derived with more care about the convergence in the sum: The sum over zeros ρ is not absolutely convergent, and is ordered in increasing $|\Im(\rho)|$.

Theorem 1.13 (Riemann-von Mangoldt explicit formula). *Let $N > 1$ be not a prime power. Then*

$$\sum_{n \leq N} \Lambda(n) = N - \lim_{T \rightarrow \infty} \sum_{|\Im(\rho)| \leq T} \frac{N^{\rho}}{\rho} - \frac{\zeta'(0)}{\zeta(0)} + \frac{1}{2} \log(1 - N^{-2}). \tag{1.7}$$

In practice, we truncate the integral in up to height T to obtained a truncated version of the explicit formula. This is obtained through integration along the choice of $c = 1 + 1/\log N$

Theorem 1.14. *Let $N > 1$. Then*

$$\sum_{n \leq N} \Lambda(n) = N - \sum_{|\Im(\rho)| \leq T} \frac{N^{\rho}}{\rho} + O\left(\frac{N}{T} (\log NT)^2\right) + O(\log N). \tag{1.8}$$

Theorems 1.13 and 1.14 are stated in [2].

The term N in the explicit formula is already suggestive of the Prime Number Theorem. The major error term comes from N^ρ in the sum, so bounding the $\Re(\rho)$ becomes the most important part in reducing the error term in the prime number theorem. This in turn is equivalent to bounding $\Re(\rho)$, and the best case is when all the zeros have real part $1/2$. This assumption is known as the Riemann Hypothesis, and has not yet been proved.

Assuming the Riemann Hypothesis, we consider the sum over the non trivial zeros

$$\left| \sum_{|\Im(\rho)| \leq T} \frac{N^\rho}{\rho} \right| \leq N^{1/2} \sum_{|\Im(\rho)| \leq T} \left| \frac{1}{\rho} \right|.$$

We know there are $\sim \log T$ zeros of height $[T, T+1)$, thus the integral $\sum |\rho^{-1}|$ behaves as

$$\sum_{n \leq T} \frac{\log n}{n} = O(\log^2 T).$$

Taking $N = T$ in the truncated explicit formula, we obtain

$$\sum_{n \leq N} \Lambda(n) = N + O(N^{1/2} \log^2 N). \quad (1.9)$$

Which implies the prime number theorem.

Remark: The PNT stated in 1.9 (with this error bound) can be shown to be equivalent to the Riemann Hypothesis.

The prime number theorem is also true without assuming the strong Riemann Hypothesis. To show this, it is sufficient to show that there are no zeros with real part 1, so the terms in the sum contributes $O(N^{1-\epsilon})$ which will be dominated by N .

Theorem 1.15. *Let $t \in \mathbb{R}$. Then $\zeta(1+it) \neq 0$.*

Proof. Let $\sigma > 1$. We consider the expressions

$$\Re \left(\frac{\zeta'}{\zeta}(\sigma + it) \right) = - \sum_n \frac{\Lambda(n)}{n^\sigma} \cos(t \log n)$$

and

$$2(1 + \cos \theta)^2 = 2 + 4 \cos \theta + 2 \cos^2 \theta = 3 + 4 \cos \theta + \cos 2\theta.$$

So that

$$\begin{aligned} \Re \left(3 \frac{\zeta'}{\zeta}(\sigma) + 4 \frac{\zeta'}{\zeta}(\sigma + it) + \frac{\zeta'}{\zeta}(\sigma + 2it) \right) &= - \sum_n \frac{\Lambda(n)}{n^\sigma} (3 + 4 \cos(t \log n) + \cos(2t \log n)) \\ &= - \sum_n \frac{\Lambda(n)}{n^\sigma} 2(1 + \cos(t \log n))^2 \\ &\leq 0. \end{aligned}$$

Now for the sake of contradiction, we let $\zeta(1+it) = 0$ be a zero of order d , and since we know ζ has a pole of order 1 at $s = 1$, we can let $t \neq 0$. Consider the function $f(s) = \zeta(s)^3 \zeta(s+it)^4 \zeta(s+2it)$. By the computation above, $\Re(f'/f) \leq 0$ when $\Re(s) > 1$. But we also have that f , by construction, has a zero of order $k \geq 4d-3 > 0$ at $s = 1$. So that $\Re(f'/f) = k/(s-1) + \text{a holomorphic part}$. Now taking $s \rightarrow 1^+$, $\Re(f'/f) \rightarrow +\infty$, contradicting $\Re(f'/f) \leq 0$. \square

Proof of the Prime Number Theorem. Let $\phi = \phi_{N,T}$ be a bump function that equals 1 on the interval $[2, N]$ and supported on $[3/2, N+N/T]$, such that $\phi^{(j)}(x) = O_j(1)$ and $\phi^{(j)}(x) = O_j(T/x)^j$ on the intervals $[3/2, 2]$ and $[N, N+N/T]$ respectively. Then

$$\sum_{n \leq N} \Lambda(n) \leq \sum_n \Lambda(n) \phi(n)$$

$$\begin{aligned}
&= \frac{-1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \tilde{\phi} \frac{\zeta'(s)}{\zeta(s)} ds \\
&= \tilde{\phi}(1) - \sum_{\rho} \tilde{\phi}(\rho) - \sum_n \tilde{\phi}(-2n)
\end{aligned}$$

The first term

$$\begin{aligned}
\tilde{\phi}(1) &= \int_0^\infty \phi(x) dx \\
&= N + O(N/T)
\end{aligned}$$

gives the term we want from the PNT. In the third term, we rewrite by Monotone Convergence

$$\begin{aligned}
\sum_n \tilde{\phi}(-2n) &= \sum_n \int_0^\infty \phi(x) x^{-2n-1} dx \\
&= \int_0^\infty \phi(x) \sum_n x^{-2n-1} dx \\
&= \int_0^\infty \phi(x) \frac{1}{x^3 - x} dx \\
&= O(1)
\end{aligned}$$

Finally, to bound the second term, we define a parameter $\bar{T} = \bar{T}(T)$ and split the sum into

$$\sum_{|\Im \rho| \leq \bar{T}} \tilde{\phi}(\rho) + \sum_{|\Im \rho| > \bar{T}} \tilde{\phi}(\rho)$$

In the first summation, we let $\epsilon = \epsilon_{\bar{T}}$ such that there are no zeros in the region $\Re(s) > 1 - \epsilon$, $|\Im(s)| \leq \bar{T}$, then

$$\begin{aligned}
\sum_{|\Im \rho| \leq \bar{T}} \tilde{\phi}(\rho) &= \sum_{|\Im \rho| \leq \bar{T}} \int_0^\infty \phi(x) x^{\rho-1} dx \\
&= O_T(N^{1-\epsilon}).
\end{aligned}$$

In the second summation, we apply integration by parts to show that

$$\begin{aligned}
\left| \int_0^\infty \phi(x) x^{\rho-1} dx \right| &= \left| \frac{1}{\rho(\rho+1)} \int_0^\infty \phi''(x) x^{\rho+1} dx \right| \\
&= O\left(\frac{1}{|\rho|^2} \frac{T^2}{N^2} \frac{N}{T} N^2 \right) \\
&= O\left(\frac{1}{|\rho|^2} T N \right)
\end{aligned}$$

The sum over $|\rho|^{-2}$ behaves as $\sum_n n^{-2} \log n$, so we can pick \bar{T} large enough depending on T to make the contribution of $\sum_{|\Im(\rho)| > \bar{T}} |\rho|^{-2}$ to be $O(T^{-2})$. So that

$$\begin{aligned}
\sum_{n \leq N} \Lambda(n) &\leq N + O(N/T) + O_T(N^{1-\epsilon}) \\
&= N + O(N/T)
\end{aligned}$$

for $N = N(T)$ sufficiently large. Similarly, repeating the same argument on $\phi = \phi_{N,T}$ equals 1 on the interval $[2, N - N/T]$ and supported on $[3/2, N]$ gives

$$\sum_{n \leq N} \Lambda(n) \geq N - O(N/T).$$

Sending $T \rightarrow \infty$ gives the PNT. □

Chapter 2

Primes in Short Intervals and Zero Density Results

2.1 Primes in Short Intervals

We would like to answer the following question about primes in short intervals. Let $y = y(x)$. What is the smallest asymptotic behavior of y such that

$$\sum_{x \leq n \leq x+y} \Lambda(n) = (1 + o(1))y \quad (2.1)$$

for large enough x ? That is, what is the shortest interval such that we have the behavior of the Prime Number Theorem? If 2.1 holds for some y , we say the Prime Number Theorem holds for intervals of y .

Remark: This question can be rephrased into finding primes in short intervals, by including a factor of $\log x$.

Proposition 2.1. *Assume the RH. Then the Prime Number Theorem holds in intervals of $x^{1/2+\epsilon}$.*

Proof. Assume the RH, then

$$\sum_{x \leq n \leq x+y} \Lambda(n) = y + O(x^{1/2} \log^2 x) = x^{1/2+\epsilon} + o(x^{1/2+\epsilon}),$$

so that the sum is non-zero for large enough x . □

Recalling that the error term is related to the real part of the zeros of the Zeta function, we motivate the following definition of zero-density:

Definition 2.2. *Let $N(\sigma, T)$ denote the number of zeros of the zeta function with real part greater than σ and imaginary part between $-T$ and T . That is,*

$$N(\sigma, T) = \#\{\rho = \beta + i\gamma \mid \beta \geq \sigma, |\gamma| \leq T\}.$$

Remark: The ideal scenario is that $N(\sigma, T) = 0$ for all $\sigma > 1/2$.

Theorem 2.3 (Littlewood [6]). *There exists a constant A such that $\zeta(\sigma + iT) \neq 0$ in the region*

$$\sigma > 1 - A \frac{\log \log |T|}{\log |T|}.$$

Theorem 2.4 (Hoheisel). *Let A be defined as in the previous theorem. Suppose that $N(\sigma, T) \ll T^{a(1-\sigma)} \log^b T$ uniformly in $1/2 \leq \sigma < 1$ and in T . Then for all*

$$\theta > 1 - \frac{1}{a + b/A},$$

the Prime Number Theorem holds in intervals of $y = x^\theta$.

This following proof is expanded from a sketch of proof in Sagun Chanillo's lecture notes [1].

Proof. First notice that $N(1/2, T)$ gets at least half of the zeros of height T , so $a \geq 2$. Let $y \ll x$. We consider the expression

$$S = S(x, y) = \frac{1}{y} \sum_{x \leq n \leq x+y} \Lambda(n).$$

By the truncated version of the explicit formula in Theorem 1.14, we get

$$S = 1 - \sum_{|\Im(\rho)| \leq T} \frac{(x+y)^\rho - x^\rho}{\rho y} + O\left(\frac{x}{yT}(\log xT)^2\right) + O\left(\frac{\log x}{y}\right).$$

We want to show that except for the constant 1 term, the remaining parts are $o(1)$. We focus on the sum over the non-trivial zeros with height less than T , and enumerate them ρ_j . For each $\rho_j = \sigma_j + it_j$, we apply the Mean Value Theorem on the function $f(x) = x_j^\rho$ to get

$$\begin{aligned} \left| \sum_{\rho_j} \frac{(x+y)^\rho - x^\rho}{\rho y} \right| &\leq \sum_{\rho_j} \left| \frac{(x+y)^{\rho_j} - x^{\rho_j}}{\rho_j y} \right| \\ &\ll \sum_{\rho_j} x^{\sigma_j-1} \\ &= \sum_{\rho_j} x^{\sigma_j-1} - x^{-1} + x^{-1} \\ &= O\left(\frac{T \log T}{x}\right) + \sum_{\rho_j} x^{\sigma_j-1} - x^{-1}. \end{aligned}$$

And by replacing $x^{\sigma_j} - 1$ by an integral,

$$\begin{aligned} \sum_{\rho_j} x^{\sigma_j-1} - x^{-1} &= \sum_{\rho_j} \int_0^{\sigma_j} x^{u-1} \log x \, du \\ &= \int_0^{1-A \frac{\log \log T}{\log T}} \sum_{\rho_j} \mathbb{1}_{u \leq \sigma_j} x^{u-1} \log x \, du \\ &= \int_0^{1-A \frac{\log \log T}{\log T}} N(u, T) x^{u-1} \log x \, du \end{aligned}$$

Where in the penultimate step we made use of Littlewood's bound and exchanged the order of integration and summation. Now we can apply the hypothesis that $N(\sigma, T) \ll T^{a(1-\sigma)} \log^b T$ for $\sigma > 1/2$ and trivially $N(\sigma, T) \ll T \log T \ll T^{a(1-\sigma)} \log^b T$ for $\sigma \leq 1/2$. This evaluates to

$$\begin{aligned} \sum_{\rho_j} x^{\sigma_j-1} - x^{-1} &\ll \int_0^{1-A \frac{\log \log T}{\log T}} T^{a(1-u)} \log^b T x^{u-1} \log x \, du \\ &= \log^b T \int_0^{1-A \frac{\log \log T}{\log T}} \left(\frac{T^a}{x}\right)^{1-u} \log x \, du \\ &= \frac{\log x \log^b T}{a \log T - \log x} \left[\frac{T^a}{x} - \left(\frac{T^a}{x}\right)^{A \frac{\log \log T}{\log T}} \right] \end{aligned}$$

Combined with the previous bounds, we have

$$S = 1 + O\left(\frac{T \log T}{x}\right) + O\left(\frac{\log x \log^b T}{a \log T - \log x} \left[\frac{T^a}{x} - \left(\frac{T^a}{x}\right)^{A \frac{\log \log T}{\log T}} \right]\right) + O\left(\frac{x}{yT}(\log xT)^2\right) + O\left(\frac{\log x}{y}\right).$$

To make all terms (except for the first) to be $o(1)$, we want to set $y = x^\theta$, $T = x^k$, such that θ, k satisfy

$$k < 1, \quad k + \theta > 1,$$

so that the second, fourth and fifth terms are $o(1)$ in x . For the third term, we require the denominator to be non zero, so we add the constraint

$$ak < 1.$$

We can simplify

$$\begin{aligned} \frac{\log x \log^b T}{a \log T - \log x} \left[\frac{T^a}{x} - \left(\frac{T^a}{x} \right)^{A \frac{\log \log T}{\log T}} \right] &= \frac{k^b \log^b x}{ak - 1} \left[x^{ak-1} - x^{(ak-1)A \frac{\log(k \log x)}{k \log x}} \right] \\ &\leq \frac{k^b \log^b x}{1 - ak} x^{ak-1} + \frac{k^b \log^b x}{1 - ak} \exp \left((ak - 1)A \frac{\log(k \log x)}{k} \right) \\ &\leq \frac{k^b \log^b x}{1 - ak} x^{ak-1} + \frac{k^b \log^b x}{1 - ak} \exp \left((ak - 1)A \frac{\log(k \log x)}{k} \right) \\ &= O(x^{ak-1}) + O \left((\log x)^{b + \frac{(ak-1)A}{k}} \right). \end{aligned}$$

We require that the last term decays in x , and this happens when

$$b + \frac{(ak - 1)A}{k} < 0 \implies (aA + b)k < A \implies k < \frac{1}{a + \frac{b}{A}}$$

We had $a \geq 2 > 1$, so this k satisfies $k < 1$ and $ak < 1$. Finally, for $k = 1/(a + bA^{-1}) - \delta/2$ we let $\theta = 1 - k + \delta$ to satisfy $\theta + k > 1$, so we can find any $1/(a + bA^{-1}) + \delta > \theta > 1 - 1/(a + bA^{-1})$, and

$$\frac{1}{y} \sum_{x \leq n \leq x+y} \Lambda(n) = S = 1 + o(1)$$

for $y = x^\theta$. This completes the proof. □

Theorem 2.4 gives the classical way to relate the distribution of primes in short intervals to the density of zeros away from the real-half line. The long-standing bound for zero density is due to separate proofs of Ingham and Huxley in 1940 and 1971 respectively:

Theorem 2.5 (Ingham bound for zero density [5]). *Let $1/2 \leq \sigma \leq 3/4$. We have*

$$N(\sigma, t) \lesssim T^{\frac{3(1-\sigma)}{2-\sigma}}.$$

Theorem 2.6 (Huxley bound for zero density [4]). *Let $3/4 \leq \sigma \leq 1$. We have*

$$N(\sigma, t) \lesssim T^{\frac{3(1-\sigma)}{3\sigma-1}}.$$

Combining these two bounds, we get the following zero density theorem.

Theorem 2.7 (Ingham-Huxley bound for zero density). *We have*

$$N(\sigma, t) \lesssim T^{\frac{12}{5}(1-\sigma)},$$

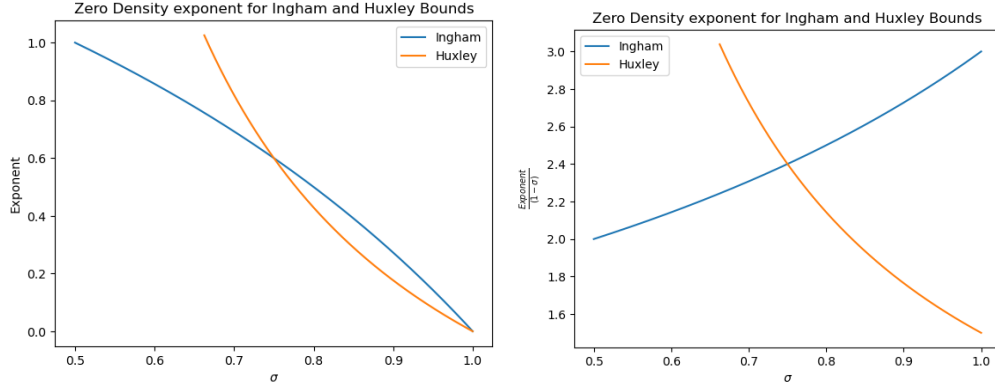

uniformly for $1/2 \leq \sigma \leq 1$

Notice that $12/5$ comes from $\sigma = 3/4$. In May 2024, Guth and Maynard published a proof that improves the Ingham-Huxley bound at $\sigma \in [7/10, 8/10]$, thus improving the result of primes in short intervals (as well as many other number theoretic results). The following sections will be dedicated to Huxley's proof of zero density, as well as Guth-Maynard's ideas in the proof. Finally, adapting from Guth and Maynard, we will provide a proof of the analogous zero-density result for L -functions.

Theorem 2.8 (Guth-Maynard bound for zero density [3]). *We have*

$$N(\sigma, t) \lesssim T^{\frac{30}{13}(1-\sigma)},$$

uniformly for $1/2 \leq \sigma \leq 1$

(a) The bounds for the exponent coincide at $\sigma = 3/4$ (b) $\sigma = 3/4$ is also the bottleneck when written in Hoheisel's form.

(c) Guth-Maynard's result improves in the range at $\sigma \in [7/10, 8/10]$. (d) The exponent is reduced around the bottleneck region.

2.2 Huxley's Proof of Zero Density

We shall prove a weaker statement of Huxley's zero density bound.

Theorem 2.9 (Huxley). *Let $\sigma \in [3/4, 1]$. We have*

$$N(\sigma, t) \lesssim T^{\frac{5\sigma-3}{\sigma^2+\sigma-1}(1-\sigma)}$$

This also gives $T^{12/5(1-\sigma)}$ when combined with Ingham's bound, as both give the same exponent $6/5$ when evaluated at $\sigma = 3/4$, but the bound given in the previous section is tighter away from $3/4$. Huxley's methodology for detecting zeros as follows. Let $M_x(s) := \sum_{n=1}^x \mu(n)n^{-s}$. Since this also converges absolutely on $\Re(s) > 1$, we can write the dirichlet series of $\zeta(s)M_x(s)$ as

$$\zeta(s)M_x(s) := \sum_n a_n n^{-s}$$

for some choice of $a_n = a_n(x)$. The zeros of its analytic continuation will contain the zeros of ζ . This may look inefficient as we may have introduced extra zeros from M_x , but the tradeoff is that we can bound these a_n 's.

Proposition 2.10. *We have*

$$\begin{cases} a_1 = 1, \\ a_n = 0, & \text{if } 1 < n \leq x, \\ |a_n| \leq d(n), & \text{if } n > x. \end{cases}$$

Proof. For all $n \leq x$, this follows from Möbius inversion. For $n > x$, we just apply the trivial bound $|\mu(d)| \leq 1$ on

$$a_n = \sum_{d|n} \mu(d).$$

□

Let $y > x$ a parameter to be choosen later, and $y \leq T^A$ for an absolute constant A . We apply the Mellin transform to

$$\begin{aligned} \sum_n a_n n^{-s} e^{-n/y} &= \frac{1}{2\pi i} \sum_n a_n n^{-s} \int_{2-i\infty}^{2+i\infty} \Gamma(w) y^w n^{-w} dw \\ &= \frac{1}{2\pi i} \int_{2-i\infty}^{2+i\infty} \zeta(s+w) M_x(s+w) \Gamma(w) y^w dw. \end{aligned}$$

If we move the line of integration to $\Re(w) = 1/2 - \Re(s)$, we get simple pole residue contributions from ζ and Γ

$$\begin{aligned} e^{-1/y} + \sum_{n>x} a_n n^{-s} e^{-n/y} &= \sum_n a_n n^{-s} e^{-n/y} = \zeta(s) M_x(s) + M_x(1) \Gamma(1-s) y^{1-s} \\ &\quad + \frac{1}{2\pi} \int_{-\infty}^{\infty} \zeta\left(\frac{1}{2} + i\Im(s) + it\right) M_x\left(\frac{1}{2} + i\Im(s) + it\right) \\ &\quad \cdot \Gamma\left(\frac{1}{2} - \Re(s) + it\right) y^{\frac{1}{2} - \Re(s) + it} dt. \end{aligned} \quad (2.2)$$

We take y large enough so that $e^{-1/y}$ is close to 1. Since $M_x(s)$ is an approximation of $1/\zeta$, we should expect that the term $\zeta(s) M_x(s)$ is about 1 most of the time and the other terms are small. However, if s is a zero of ζ , then $\zeta(s) M_x(s) = 0$, so at least one of the following things need to happen

- (i) $|\sum_{n>x} a_n n^{-s} e^{-n/y}|$ is large.
- (ii) The integral in t is large.
- (iii) $|M_x(1) \Gamma(1-s) y^{1-s}|$ is large.

We thus transform the problem of detecting zeros to counting the number of occurences of extreme values. We will later see that type (iii) zeros are negligible, so we need to bound the number of type (i) and type (ii) zeros. To bound the occurences of extreme values, we introduce the following two lemmas.

Lemma 2.11. *Let $W = \{t_j\} \subseteq [0, T]$ be a one-separated set such that*

$$\left| \zeta\left(\frac{1}{2} + it_j\right) \right| > V \quad \forall j,$$

then

$$|W| \lesssim TV^{-4}.$$

Proof. By corollary 10.4 of [7], we have

$$WV^4 \leq \sum_{t \in W} \left| \zeta\left(\frac{1}{2} + it_j\right) \right|^4 \ll T(\log T)^5.$$

The result follows immediately. □

Lemma 2.12 (Halász Inequality). *Let a be an arithmetic function, and $D_N(s) = \sum_{n \leq N} a(n) n^s$, and $G = \sum_{n \leq N} |a(n)|^2$. If $W = \{t_j\} \subseteq [0, T]$ is a one-separated set such that*

$$|D_N(it_j)| > V \quad \forall j,$$

then

$$|W| \lesssim GNV^{-2} + G^3 NTV^{-6}.$$

This is equation 2.9 from [4].

Proof of Huxley's Zero Density Theorem. From equation 2.2, we take $y > 6$ so that $e^{-1/y} > 5/6$. We also truncate the sum in $n > x$ to $x < n \leq y^2$ with an error of $1/6$ for large enough y . Finally, by the rapid decay of Γ , we truncate the integral in t to the range $|t| \leq B \log T$ with an error of $1/6$. Thus, s is a zero only if

- (i) $|\sum_{x < n \leq y^2} a_n n^{-s} e^{-n/y}| \geq \frac{1}{6}$, or
- (ii) $\frac{1}{2\pi} |\int_{-B \log T}^{B \log T} \zeta(\frac{1}{2} + i\Im(s) + it) M_x(\frac{1}{2} + i\Im(s) + it) \Gamma(\frac{1}{2} - \Re(s) + it) y^{\frac{1}{2} - \Re(s) + it} dt| \geq \frac{1}{6}$, or
- (iii) $|M_x(1) \Gamma(1-s) y^{1-s}| \geq \frac{1}{6}$.

Of the zeros $\rho = \beta + i\gamma$ of ζ in the region, at the cost of a factor of $\log^2 T$, we take representatives such that if $\rho_1 \neq \rho_2$ then $|\rho_1 - \rho_2| \gtrsim 1$.

For Class (iii) zeros, we use Stirling's formula on Γ to get

$$\log \Gamma(1-s) = \left(\frac{1}{2} - s\right) \log(1-s) + s - \frac{1}{2} \log 2\pi + O(|s|^{-1}).$$

. Therefore, the $\Gamma(1-s)$ decays at the rate of $O(|s|^{1/2-\sigma})$. Therefore, the large values can only happen in the range $\Im(s) \lesssim 1$ and so we can bound the occurrences of these zeros to be $O(T^\epsilon)$. Therefore, this is negligible.

For Class (i) zeros, we split the sum dyadically to get

$$\left| \sum_{n \sim U, n \leq y^2} a(n) n^{-\rho} e^{n/y} \right| \geq O((\log T)^{-1}), \quad (2.3)$$

for some $x \leq U = 2^k \leq y$. Currently, the zeros do not have the same real part. However, we can remove the dependence of β by introducing a bump function $\phi(x)$ that equals $e^{x(\beta-\sigma)}$ on $\log x \sim U$, so that

$$\begin{aligned} \sum_{n \sim U} a(n) n^{-\rho} e^{n/y} &= \sum_{n \sim U} a(n) n^{-\sigma - i\gamma} e^{n/y} \phi(\log n) \\ &= \sum_{n \sim U} a(n) n^{-\sigma - i\gamma} e^{n/y} \int \hat{\phi}(\xi) e(\xi \log n) d\xi \\ &= \int \hat{\phi}(\xi) \sum_{n \sim U} a(n) n^{-\sigma - i\gamma - 2\pi i \xi} e^{n/y} d\xi \\ &= \int_{|\xi| \lesssim 1} \hat{\phi}(\xi) \sum_{n \sim U} a(n) n^{-\sigma - i\gamma - 2\pi i \xi} e^{n/y} d\xi + O_{\epsilon, A}(T^{-A}). \end{aligned}$$

$\hat{\phi}$ is bounded by $O(\log U)$, so this log factor is negligible compared to T^ϵ . Applying the ML estimate on the integral gives there is a value $|\xi| \lesssim 1$ such that

$$\sum_{n \sim U} a(n) n^{-\sigma - i\gamma - 2\pi i \xi} e^{n/y} d\xi \gg T^{-\epsilon}.$$

Therefore, we can assume that all the zeros have real part σ without affecting the argument. Applying Lemma 2.12, we get that the number of times that equation 2.3 can happen for each U is

$$\lesssim U^{2-2\sigma} + U^{4-6\sigma} T \lesssim y^{2-2\sigma} + x^{4-6\sigma} T.$$

Note that $\sigma \geq 3/4$, so that $4 - 6\sigma < 0$, so $x^{4-6\sigma}$ is used instead of $y^{4-6\sigma}$. For Class (ii) zeros, we apply ML estimate to see that for each zero $\rho_j = \beta_j + i\gamma_j$ there $|t_j - \gamma_j| \ll \log T$ such that

$$\zeta\left(\frac{1}{2} + i\gamma_j + it_j\right) M_x\left(\frac{1}{2} + i\gamma_j + it_j\right) \gg y^{\Re(s) - \frac{1}{2}} / \log T \gg y^{\sigma - \frac{1}{2}} / \log T,$$

Therefore, we can consider a new set of 'zeros' $\sigma + i(\gamma_j + t_j)$, and make them 1-separated at a cost of a factor of $O(\log T)$. We separate these 'zeros' into two cases

- (a) $\zeta(\frac{1}{2} + i\gamma_j + it_j) \geq A$,
- (b) $M_x(\frac{1}{2} + i\gamma_j + it_j) \geq B$.

where $AB \gg y^{\sigma-\frac{1}{2}}/\log T$. For case A zeros, this is bounded by corollary 2.11 to be

$$\lesssim TA^{-4}.$$

For case B zeros, we reapply lemma 2.12 to bound this by

$$\lesssim xB^{-2} + xTB^{-6}.$$

Here, we took G to be $O(\sum_{n \leq x} d(n)n^{-1})$. The divisor function grows slower than any n^ϵ , so $G \lesssim 1$. Combined with type 1 zeros, we have

$$N(\sigma, T) \lesssim y^{2-2\sigma} + x^{4-6\sigma}T + TA^{-4} + xB^{-2} + xTB^{-6}.$$

We first consider the terms with A and B . We take $B^4 \ll T$, so that $xB^{-2} \ll xTB^{-6}$. We can also replace TA^{-4} with $TB^4y^{2-4\sigma}$ to get

$$N(\sigma, T) \lesssim y^{2-2\sigma} + x^{4-6\sigma}T + TB^4y^{2-4\sigma} + xTB^{-6}.$$

We take $B = (xy^{4\sigma-2})^{1/10}$, so that the last two terms are of the same magnitude

$$O(Tx^{2/5}y^{(6-12\sigma)/5}).$$

In our new bound

$$N(\sigma, T) \lesssim y^{2-2\sigma} + x^{4-6\sigma}T + Tx^{2/5}y^{(6-12\sigma)/5},$$

we remove the dependence on x by setting

$$x = y^{\frac{(6-12\sigma)/5}{4-2/5-6\sigma}} = y^{\frac{1-2\sigma}{3-5\sigma}},$$

so that the last two terms are of the same magnitude. Finally,

$$N(\sigma, T) \lesssim y^{2-2\sigma} + y^{\frac{(1-2\sigma)(4-6\sigma)}{3-5\sigma}}T,$$

we set

$$y = T^{\frac{5\sigma-3}{2(\sigma^2+\sigma-1)}}$$

so that the last two terms combine into one bound

$$N(\sigma, T) \lesssim T^{\frac{(5\sigma-3)(1-\sigma)}{(\sigma^2+\sigma-1)}}.$$

When $\sigma = 3/4$, we have

$$\frac{(5\sigma-3)}{(\sigma^2+\sigma-1)} = \frac{12}{5},$$

and the first derivative test gives that this function is decreasing in σ in the range $\sigma \in [3/4, 1]$. Finally, we have to check the conditions

$$x < y, \quad B^4 \ll T.$$

The first condition is true as $(1-2\sigma)/(3-5\sigma) < 1$ in this range. The second condition is true as

$$B^4 = (xy^{4\sigma-2})^{2/5} = (y^{4\sigma-2+\frac{(6-12\sigma)/5}{4-2/5-6\sigma}})^{2/5} = T^{\frac{2}{5}\frac{5\sigma-3}{2(\sigma^2+\sigma-1)}(4\sigma-2+\frac{(6-12\sigma)/5}{4-2/5-6\sigma})} = T^{\frac{(3\sigma-2)(\sigma-1)}{\sigma^2+\sigma-1}} \ll T$$

in this range. □

Chapter 3

Guth-Maynard's Proof of the Zero Density near $\sigma = 3/4$

In May 2024, Guth and Maynard published an improvement of the large values of Dirichlet polynomials estimate at $\sigma \in [7/10, 8/10]$.

Theorem 3.1 (Guth-Maynard Large Values Estimate). *Let (b_n) be a sequence of complex numbers such that $|b_n| \leq 1$ for all n , and $W = \{t_j\}_{j=1}^{|W|}$ be a 1-separated set $\subseteq [0, T]$, such that*

$$\left| \sum_{n \sim N} b_n n^{it_j} \right| \geq V$$

for each $t_j \in W$. Then

$$|W| \lesssim N^2 V^{-2} + N^{18/5} V^{-4} + TN^{12/5} V^{-4}.$$

Let us compare this bound to Lemma 2.12, which states

$$|W| \lesssim N^2 V^{-2} + TN^4 V^{-6}.$$

In the critical case $V = N^{3/4}$, $N \leq T^{5/6-\epsilon}$, the original bound will give

$$|W| \lesssim N^2 N^{-3/2} + TN^4 N^{-9/2} \lesssim N^{1/2} + TN^{-1/2} \lesssim TN^{-1/2},$$

while the bound by Guth and Maynard gives

$$|W| \lesssim N^2 N^{-3/2} + N^{18/5} N^{-3} + TN^{12/5} N^{-3} \lesssim N^{1/2} + TN^{-3/5} \lesssim TN^{-3/5}.$$

This new theorem, when applied in Huxley's proof in the previous chapter, gives an improvement in the bound of zero density in the range $\sigma \in [7/10, 8/10]$.

3.1 Outline and Sketch of proof

The structure of the proof can be broken down as follows: We first notice that $|W|$ is bounded by the operator norm of a matrix M . This operator norm, using results from linear algebra, is bounded by the trace. Applying Poisson summation on the trace gives 4 terms that are separately handled, which we will name S_0 to S_3 . We will see that S_0 gives the 'main term' that is consistent with the density hypothesis, S_1 is negligible, S_2 is bounded by a theorem by Heath-Brown, which we state below.

Theorem 3.2 (Heath-Brown). *Let $\mathcal{S} = \{(t_j, \chi_j)\}$ be one-separate, primitive characters of modulus q . Then*

$$\sum_{\substack{(t_1, \chi_1) \\ (t_2, \chi_2)}} \left| \sum_{n=1}^N b_n n^{-i(t_1-t_2)} \chi_1 \bar{\chi}_2(n) \right|^2 \lesssim |\mathcal{S}| N^2 + |\mathcal{S}|^2 N + |\mathcal{S}|^{5/4} (qT)^{1/2} N.$$

The most tricky term, S_3 is a summation over a three-dimensional lattice. We will see that S_3 is bounded by what is known as the *additive energy* of the set W , defined by

$$E(W) := \#\{t_1, t_2, t_3, t_4 \in W : |t_1 + t_2 - t_3 - t_4| \ll T^\epsilon\}.$$

This term describes the ‘additive structure’ of W . We see that $E(W)$ is bounded below by $|W|^2$, as the condition is satisfied when $t_1 = t_3$ and $t_2 = t_4$. Moreover, since W is 1-separated, the choice of t_1, t_2, t_3 fixes $O(1)$ choices for t_4 , so $E(W)$ is bounded above by $|W|^3$. In the extreme case that the additive structure of W is high, such as when $t_j = j\alpha$ for a constant α , the energy of the set is $O(|W|^3)$. This definition naturally arises from taking the fourth moment of the function

$$R(v) := \sum_{t \in W} v^{it}.$$

This gives us

$$R(v)^4 = \sum_{t_1, t_2, t_3, t_4 \in W} v^{i(t_1 + t_2 - t_3 - t_4)}.$$

The naive choice $E(W) \leq W^3$ is slightly too loose to beat the Ingham-Huxley bound. However, an orthogonal bound can be found for $E(W)$ based on Heath-Brown’s theorem. Finally, the bound in 7 and 8 combined is enough to give an improvement in most cases, a further refinement of the S_3 bound was required. This relies on the averaging over the affine summations of R .

$$\sup_{0 < M_1, M_2, M_3 < M} \int \left(\sum_{\substack{|m_1| \sim M_1 \\ |m_2| \sim M_2 \\ |m_3| \ll M_3}} \left| R\left(\frac{m_1 u + m_3}{m_2}\right) \right| \right)^2 du \lesssim M^6 \|R\|_{L_2}^4 + M^4 \|f\|_{L_4}^4.$$

We give a quick sketch of the whole proof below. In the next section, we will give a full proof of the generalized statement of the theorem that considers primitive Dirichlet characters mod q . The proof of Guth-Maynard can be recovered by using the special case $q = 1$.

0. Setup

First, as in the theorem, we let (b_n) be a sequence of complex numbers such that $|b_n| \leq 1$ for all n ,

$$D_n(t) := \sum_{n \sim N} b_n n^{it},$$

$W = \{t_j\}_{j=1}^{|W|}$ be a T^ϵ -separated set $\subseteq [0, T]$, such that

$$|D_n(t_j)| \geq V$$

for each $t_j \in W$. Notice that we now let the set be T^ϵ separated for $\epsilon > 0$. This means that we will give up a factor of T^ϵ in the final bound, but this makes many computations cleaner as this T^ϵ dominates the log factors. Moreover, we can introduce a bump function ω with support in $[1, 2]$ to localize the summation, and rewrite

$$D_n(t_j) = \sum_n \omega\left(\frac{n}{N}\right) b_n n^{it_j}.$$

This is added for the Poisson summation in step 3.

1. Bounding $|W|$ with operator norm

We view $\vec{b} = (b_n)_{n \sim N}$ as a N -dimensional vector, and consider the $|W| \times N$ matrix, indexed by j from 1 to $|W|$ and $n \sim N$,

$$M_{j,n} = n^{it_j} = \omega\left(\frac{n}{N}\right) n^{it_j}.$$

Figure 3.1: Graphical representation of Guth-Maynard proof outline

Then we can view the j -th entry of the product $M\vec{b}$ as $D_n(t_j)$. In other words

$$|M\vec{b}|^2 \geq V^2|W|.$$

However, we can bound $|M\vec{b}|$ using the operator norm of M and $|b_n| \leq 1$ to get

$$|M\vec{b}|^2 \leq \|M\|^2|\vec{b}|^2 \leq \|M\|^2 N.$$

Combined with the previous inequality, we get

$$|W| \leq \|M\|^2 NV^{-2}. \quad (3.1)$$

2. Bounding $\|M\|$

An immediate way to proceed is to note that $\|M\|^2$ is the largest eigenvalue of MM^* , which in turn is bounded by sum of eigenvalues which is the trace of M^*M . However, this is somewhat inefficient. Consider N -dimensional vector that enumerates through the eigenvalues (λ_n) of MM^* , so that the trace will be the L_1 norm of this vector. In principle, we would like the L_∞ norm of this vector, so we can try to take L_k

norms of this vector for big k to get close to L_∞ . Using an eigenbasis for MM^* , we can see that the L_k norm is represented by

$$\left(\sum_{n \sim N} \lambda_n^k \right)^{1/k} = \text{Tr}((MM^*)^k)^{1/k}.$$

We take $k = 3$, which is the highest power we can afford given the tools at our disposal. This gives

$$|W| \leq \text{Tr}((MM^*)^3)^{1/3} NV^{-2}. \quad (3.2)$$

3. Expansion of $\text{Tr}((MM^*)^3)$

We first compute

$$(MM^*)_{n_1, n_2} = \sum_{t \in W} \omega\left(\frac{n_1}{N}\right) \omega\left(\frac{n_2}{N}\right) n_1^{-it_j} n_2^{it_j}$$

so that

$$\begin{aligned} \text{tr}((M^*M)^3) &= \sum_{t_1, t_2, t_3 \in W} \sum_{n_1, n_2, n_3 \sim N} \omega\left(\frac{n_1}{N}\right)^2 \omega\left(\frac{n_2}{N}\right)^2 \omega\left(\frac{n_3}{N}\right)^2 n_1^{i(t_1-t_3)} n_2^{i(t_2-t_1)} n_3^{i(t_3-t_2)} \\ &= \sum_{t_1, t_2, t_3 \in W} \sum_{n_1, n_2, n_3} \omega\left(\frac{n_1}{N}\right)^2 \omega\left(\frac{n_2}{N}\right)^2 \omega\left(\frac{n_3}{N}\right)^2 \left(\frac{n_1}{N}\right)^{i(t_1-t_3)} \left(\frac{n_2}{N}\right)^{i(t_2-t_1)} \left(\frac{n_3}{N}\right)^{i(t_3-t_2)}. \end{aligned}$$

Let $h_t(u) := \omega(u)^2 u^{it}$, we can apply Poisson summation in the inner integral over n_1, n_2, n_3 to get

$$\text{tr}((M^*M)^3) = N^3 \sum_{t_1, t_2, t_3 \in W} \sum_{m_1, m_2, m_3} \hat{h}_{t_1-t_3}(Nm_1) \hat{h}_{t_2-t_1}(Nm_2) \hat{h}_{t_3-t_2}(Nm_3). \quad (3.3)$$

What we can gain here is that $\hat{h}_t m$ has decay in t or m based on the principle of non-stationary phase.

Lemma 3.3 (Non-stationary phase). *We have for any integer $A > 0$*

$$\begin{aligned} |\hat{h}_t(\xi)| &\ll_A \frac{1 + |t|^A}{|\xi|^A}, \\ |\hat{h}_t(\xi)| &\ll_A \frac{1 + |\xi|^A}{|t|^A}. \end{aligned}$$

Proof. We have

$$\hat{h}_t(\xi) = \int \omega(u)^2 u^{it} e^{2\pi i \xi u} du.$$

By repeated integration by parts on $\omega(u)^2 u^{it}$ and $e^{2\pi i \xi u}$, we get

$$|\hat{h}_t(\xi)| = \left| \int (2\pi i \xi)^{-A} e^{2\pi i \xi u} \frac{d^A}{(du)^A} (\omega^2(u) u^{it}) du \right| \ll_A \frac{1 + |t|^A}{|\xi|^A}.$$

A similar argument for integration by parts on $\omega(u)^2 e^{2\pi i \xi u}$ and u^{it} gives

$$|\hat{h}_t(\xi)| = \left| \int \frac{1}{(it+1)(it+2)\dots(it+A)} u^{it+A} \frac{d^A}{(du)^A} (\omega^2(u) e^{2\pi i \xi u}) du \right| \ll_A \frac{1 + |\xi|^A}{|t|^A}.$$

□

This means that we can handle terms in equation 3.3 if m_i is small and $t_j - t_k$ is big, or m_i is big and $t_j - t_k$ is small. With this in mind, we split the sum over m_1, m_2, m_3 in the equation into four parts. S_0 , where all three m terms are zero, S_1 , where exactly one of the m terms is non-zero, S_2 , where exactly two of the m terms are non-zero, and S_3 , where all three m terms are non-zero. That is,

$$\text{tr}((M^*M)^3) = S_0 + S_1 + S_2 + S_3,$$

where

$$S_j = N^3 \sum_{m_1, m_2, m_3, \#\{m_k=0\}=j} I_m,$$

$$I_m = I_{(m_1, m_2, m_3)} := N^3 \sum_{t_1, t_2, t_3 \in W} \hat{h}_{t_1-t_3}(Nm_1) \hat{h}_{t_2-t_1}(Nm_2) \hat{h}_{t_3-t_2}(Nm_3).$$

4. Bounding S_0

S_0 only has one term in the sum.

$$S_0 = N^3 \sum_{t_1, t_2, t_3 \in W} \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2}(0)$$

Now we can apply that W is T^ϵ separated, so there is a trivial bound $|W| \leq T$ and $\hat{h}_{t_j-t_k}$ is negligible by the principle of non-stationary phase. So we can only consider

$$S_0 = N^3 \sum_{t \in W} \hat{h}_0(0) + O(T^{-100}) = N^3 |W| \|\omega\|_{L_2}^6.$$

Taking the cube root, this term gives $O(N^2 V^{-2} |W|)$ in equation 3.2. This is strikingly similar to the $N^2 V^{-2}$ term that the density hypothesis conjectures. Guth and Maynard isolates this term by introducing the following lemma.

Lemma 3.4. *Let A be an $m \times n$ matrix. Then*

$$\|A\| \leq 2 \left(\text{tr}((AA^*)^3) - \frac{\text{tr}(AA^*)^3}{m^2} \right)^{1/6} + 2 \left(\frac{\text{tr}(AA^*)}{m} \right)^{1/2}.$$

Proof. This is Lemma 4.2 from Guth-Maynard. [**<empty citation>**]

□

Applying this lemma, we can compute that

$$\text{tr}(MM^*) = \sum_{n \sim N} \sum_{t \in W} \omega\left(\frac{n}{N}\right)^2 n^{-it} n^{it} = |W| \sum_n \omega\left(\frac{n}{N}\right)^2.$$

Applying Poisson summation, this equals

$$|W| \sum_m N \hat{h}_0(mN).$$

By non-stationary phase use the rapid decay of $\hat{h}_0(\xi)$ in ξ to only consider the term $m = 0$ at the cost of N^{-100} . Therefore, $\text{tr}(MM^*) = |W|N \|\omega\|_{L_2}^2 + O(N^{-100})$. Lemma 3.4 gives

$$|W| \ll NV^{-2} (N + (S_0 + S_1 + S_2 + S_3 - N^3 \|\omega\|_{L_2}^6 |W|)^{1/3}) \ll N^2 V^{-2} + NV^{-2} (S_1 + S_2 + S_3)^{1/3}.$$

5. Bounding S_1

By symmetry in m_1, m_2, m_3 , we can consider the terms where $m_3 \neq 0$ at a cost of a factor of 3. Then

$$S_1 = 3N^3 \sum_{m \neq 0} \sum_{t_1, t_2, t_3 \in W} \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2}(mN).$$

This term is bounded by non-stationary phase. If $|m| > T^{1+\epsilon}/N$, then $|m|/|t_3 - t_2| < T^\epsilon$, so we can truncate the sum to $|m| \leq T^{1+\epsilon}/N$ with an error of $O_\epsilon(T^{-100})$. In this range, if $t_1 \neq t_3$ or $t_2 \neq t_1$, then they are T^ϵ apart, then we get rapid decay in $\hat{h}_{t_1-t_3}(0)$ or $\hat{h}_{t_2-t_1}(0)$ to be $O_\epsilon T^{-100}$. But when $t_1 = t_2 = t_3$, we get decay in the last term $\hat{h}_0(mN)$. Combining all cases, this term is negligible.

6. Bounding S_2

By symmetry again we can consider the terms where $m_1, m_2 \neq 0, m_3 = 0$. Then

$$S_2 = 3N^3 \sum_{m_1, m_2 \neq 0} \sum_{t_1, t_2, t_3 \in W} \hat{h}_{t_1-t_3}(m_1 N) \hat{h}_{t_2-t_1}(m_2 N) \hat{h}_{t_3-t_2}(0).$$

Due to decay of the last term in $|t_3 - t_2|$, we can only consider the terms $t_3 = t_2$ with error $O_{\epsilon, A}(T^{-A})$. Then we can rewrite

$$\begin{aligned} 3N^3 \hat{h}_0(0) \sum_{m_1, m_2 \neq 0} \sum_{t_1, t_2 \in W} \hat{h}_{t_1-t_2}(m_1 N) \hat{h}_{t_2-t_1}(m_2 N) &= 3N^3 \hat{h}_0(0) \sum_{m_1, m_2 \neq 0} \sum_{t_1, t_2 \in W} \hat{h}_{t_1-t_2}(m_1 N) \hat{h}_{t_1-t_2}(-m_2 N) \\ &= 3N^3 \hat{h}_0(0) \sum_{t_1, t_2 \in W} \left(\sum_{m \neq 0} \hat{h}_{t_1-t_2}(m N) \right)^2. \end{aligned}$$

Poisson summation gives

$$N \sum_m \hat{h}_{t_1-t_2}(m N) = \sum_n h_{t_1-t_2}\left(\frac{n}{N}\right) = \sum_n \omega\left(\frac{n}{N}\right) n^{i(t_1-t_2)}.$$

Therefore, a direct application of Heath Brown's theorem 3.2 gives a bound for S_2 . Here we have added in the terms for $m = 0$, which is insignificant when t_1 and t_2 are T^ϵ separated. However, this is somewhat lossy for terms $t_1 = t_2$. However, we can ignore the terms with $t_1 = t_2$ at a small error due to the rapid decay in $\hat{h}_{t_1-t_2}(m N)$, apply Poisson summation, then add the terms $t_1 = t_2$ again.

7. Bounding S_3

S_3 sums over most points on the 3-dimensional lattice. By symmetry, we can consider only the terms with $|m_1| \leq |m_2| \leq |m_3|$ with an error factor of 6. Recall that

$$I_m = N^3 \sum_{t_1, t_2, t_3 \in W} \hat{h}_{t_1-t_3}(N m_1) \hat{h}_{t_2-t_1}(N m_2) \hat{h}_{t_3-t_2}(N m_3).$$

By the principle of non-stationary phase, we can truncate the sum across I_m to $|m_1|, |m_2|, |m_3| \lesssim T/N$, at the cost of $O_\epsilon(T^{-100})$, as $t_j - t_k = O(T)$. We expand \hat{h} in integral form, so that

$$\begin{aligned} I_{\vec{m}} &= N^3 \sum_{t_1, t_2, t_3 \in W} \int_{\mathbb{R}^3} \omega(u_1)^2 \omega(u_2)^2 \omega(u_3)^2 u_1^{i(t_1-t_3)} u_2^{i(t_2-t_1)} u_3^{i(t_3-t_2)} e(-N \vec{m} \cdot \vec{u}) d\vec{u} \\ &= N^3 \sum_{t_1, t_2, t_3 \in W} \int_{\mathbb{R}^3} \tilde{\omega}(\vec{u}) \left(\frac{u_1}{u_2}\right)^{it_1} \left(\frac{u_2}{u_3}\right)^{it_2} \left(\frac{u_3}{u_1}\right)^{it_3} e(-N \vec{m} \cdot \vec{u}) d\vec{u} \end{aligned}$$

For $\tilde{\omega}(\vec{u}) = \omega(u_1)^2 \omega(u_2)^2 \omega(u_3)^2$. Because $\tilde{\omega}$ is supported away from $u_3 = 0$, we can introduce the change of variables $v_1 = u_1/u_3$, $v_2 = u_2/u_3$. The Jacobian is u_3^2 , and $u_1/u_2 = v_1/v_2$, so that

$$\begin{aligned} I_{\vec{m}} &= N^3 \sum_{t_1, t_2, t_3 \in W} \int_{\mathbb{R}^3} u_3^2 \tilde{\omega}(v_1 u_3, v_2 u_3, u_3) \left(\frac{v_1}{v_2}\right)^{it_1} v_2^{it_2} \left(\frac{1}{v_1}\right)^{it_3} e(-N u_3(m_1 v_1 + m_2 v_2 + m_3)) dv_1 dv_2 du_3 \\ &= N^3 \sum_{t_1, t_2, t_3 \in W} \int_{\mathbb{R}^2} \int_{\mathbb{R}} u_3^2 \tilde{\omega}(v_1 u_3, v_2 u_3, u_3) e(-N u_3(m_1 v_1 + m_2 v_2 + m_3)) du_3 \left(\frac{v_1}{v_2}\right)^{it_1} v_2^{it_2} \left(\frac{1}{v_1}\right)^{it_3} dv_1 dv_2 \end{aligned}$$

The inner integral in u_3 places restrictions on the domain of integration. First, the support of $\tilde{\omega}$ is $[1, 2] \times [1, 2] \times [1, 2]$. Thus, if it is non-zero, we have $v_1 u_3, v_2 u_3, u_3 \in [1, 2] \implies v_1, v_2 \in [1/2, 2]$. Therefore, we can restrict the outer integral in v_1 and v_2 to this range. Next, since $v_1, v_2 = O(1)$, the chain rule gives

$$\left(\frac{\partial}{\partial u_3}\right)^j \omega(v_1 u_3, v_2 u_3, u_3) \ll_j 1.$$

Therefore, we can apply the repeated integration by parts to get rapid decay of the integral in $|N(m_1v_1 + m_2v_2 + m_3)|$. In particular, we can truncate the integral to the range $|N(m_1v_1 + m_2v_2 + m_3)| \ll T^\epsilon$ at an error of $O_\epsilon(T^{-100})$, and use

$$\int_{\mathbb{R}} u_3^2 \tilde{\omega}(v_1u_3, v_2u_3, u_3) e(-Nu_3(m_1v_1 + m_2v_2 + m_3)) du_3 = O(1)$$

in this range by the compact support of $\tilde{\omega}$. This gives us

$$|I_{\tilde{m}}| \leq \left| N^3 \sum_{t_1, t_2, t_3 \in W} \int_{\substack{|v_1m_1 + v_2m_2 + m_3| \lesssim \frac{1}{N} \\ \frac{1}{2} \leq v_1, v_2 \leq 2}} \left(\frac{v_1}{v_2}\right)^{it_1} v_2^{it_2} \left(\frac{1}{v_1}\right)^{it_3} dv_1 dv_2 \right| + O_\epsilon(T^{-100}). \quad (3.4)$$

Recall that in the outline we defined

$$R(v) := \sum_{t \in W} v^{it}.$$

Exchanging the summation and integral, we get the term

$$\begin{aligned} & \left| N^3 \int_{\substack{|v_1m_1 + v_2m_2 + m_3| \lesssim \frac{1}{N} \\ \frac{1}{2} \leq v_1, v_2 \leq 2}} R\left(\frac{v_1}{v_2}\right) R(v_2) R\left(\frac{1}{v_1}\right) dv_1 dv_2 \right| \\ & \leq N^3 \int_{\substack{|v_1m_1 + v_2m_2 + m_3| \lesssim \frac{1}{N} \\ \frac{1}{2} \leq v_1, v_2 \leq 2}} \left| R\left(\frac{v_1}{v_2}\right) R(v_2) R\left(\frac{1}{v_1}\right) \right| dv_1 dv_2 \\ & = N^3 \int_{\substack{|v_1m_1 + v_2m_2 + m_3| \lesssim \frac{1}{N} \\ \frac{1}{2} \leq v_1, v_2 \leq 2}} \left| R\left(\frac{v_2}{v_1}\right) R(v_2) R(v_1) \right| dv_1 dv_2, \end{aligned}$$

where the last step, we used

$$|R(v^{-1})| = \left| \sum_{t \in W} v^{-it} \right| = \left| \sum_{t \in W} v^{it} \right| = |R(v)|.$$

Now we fix v_1 , and consider the integral in v_2 in the range

$$|v_1m_1 + v_2m_2 + m_3| \lesssim \frac{1}{N} \implies \left| v_2 - \frac{v_1m_1 + m_3}{-m_2} \right| \lesssim \frac{1}{|m_2|N}.$$

If we enforce the conditions $|m_1| \leq |m_2| \leq |m_3|$ and $v_2 \asymp 1$, we see that the domain of integration is empty unless $|m_2| \asymp |m_3|$. Thus, we can break the sum across

$$\sum_{|m_1|, |m_2|, |m_3| \lesssim T/N}$$

to be

$$\log T^{1+\epsilon}/N \sup_{U=2^j, V \leq U} \sum_{\substack{|m_1| \sim V \\ |m_2|, |m_3| \sim U}}.$$

Moreover, we integrate in v_2 over a very small neighborhood of width $\lesssim 1/(|m_2|N)$ around $v_2 = (v_1m_1 + m_3)/(-m_2)$. In principle, we can estimate this integral by taking the value of R at this point to get

$$\approx \frac{1}{|m_2|N} \int_{\frac{1}{2} \leq v_1 \leq 2} \left| R\left(\frac{v_1m_1 + m_3}{-v_1m_2}\right) R\left(\frac{v_1m_1 + m_3}{-m_2}\right) R(v_1) \right| dv_1.$$

This is made precise by apply to a $(1/N|m_2|)$ -smoothened version of R , stated in Proposition 4.18. Finally, Hölder's inequality gives a bound of

$$\left\| R\left(\frac{vm_1 + m_3}{-vm_2}\right) \right\|_{L_4, v \asymp 1} \left\| R\left(\frac{vm_1 + m_3}{-m_2}\right) \right\|_{L_4, v_1 \asymp 1} \left\| R(v) \right\|_{L_2, v_1 \asymp 1}$$

The second moment of R is bounded by the size of W . Indeed, we have

$$\int_{v \asymp 1} |R(v)|^2 dv = \sum_{t_1, t_2 \in W} \int_{v \asymp 1} v^{i(t_1 - t_2)} dv.$$

If $t_1 - t_2 \neq 0$, then $|t_1 - t_2| > T^\epsilon$, so the oscillatory integral will be negligible by the fast decay. There are $|W|$ terms satisfying $t_1 = t_2$, and each contributes $O(1)$ to the sum. Similarly, the fourth moment of R is bounded by the energy, recalling its definition

$$E(W) := \#\{t_1, t_2, t_3, t_4 \in W : |t_1 + t_2 - t_3 - t_4| \ll T^\epsilon\}.$$

We get

$$\int_{v \asymp 1} |R(v)|^4 dv = \sum_{t_1, t_2, t_3, t_4 \in W} \int_{v \asymp 1} v^{i(t_1 + t_2 - t_3 - t_4)} dv,$$

and the terms in the summation are negligible unless $|t_1 + t_2 - t_3 - t_4| \ll T^\epsilon$. Assembling everything together gives an initial bound of

$$S_3 \lesssim N^3 \sum_{|m_1| \sim V, |m_2| \sim V, |m_3| \sim V} \frac{1}{|m_2|N} E(W)^{1/2} |W|^{1/2} \lesssim T^2 E(W)^{1/2} |W|^{1/2},$$

recalling that $U, V \lesssim T/N$.

9. Refinement of S_3 bound

Recall that in the previous section, we summed across

$$\sum_{\substack{|m_1| \sim V \\ |m_2|, |m_3| \sim U}} \frac{N}{|m_2|} \int_{\frac{1}{2} \leq v_1 \leq 2} \left| R\left(\frac{v_1 m_1 + m_3}{-v_1 m_2}\right) R\left(\frac{v_1 m_1 + m_3}{-m_2}\right) R(v_1) \right| dv_1$$

By repeatedly applying Cauchy-Schwartz, we can move the summation into the integral and obtain terms that resembles the form

$$\int_{v_1 \asymp 1} \left(\sum_{\substack{|m_1| \sim V \\ |m_2|, |m_3| \sim U}} \left| R\left(\frac{v_1 m_1 + m_3}{-m_2}\right) \right|^2 \right) dv_1.$$

The term $(v_1 m_1 + m_3)/(-m_2)$ describes an affine transformation in v_1 . Intuitively, thus averaging over all the affine transformations is can be expressed as the expected value of a random variable squared, where the random variable

$$X := X(v_1) := \sum_{\substack{|m_1| \sim V \\ |m_2|, |m_3| \sim U}} \left| R\left(\frac{v_1 m_1 + m_3}{-m_2}\right) \right|^2,$$

and the measure is uniform across $v_1 \asymp 1$. This can be split up to get

$$E[X^2] = E[X]^2 + \text{Var}(X).$$

Indeed, we have Lemma 3.5 that gives us this estimate. By a change of variables, the expected value of X is represented by $M^3 \int_{u \asymp 1} R(u)^2 du$.

Lemma 3.5. *Let $M > 0$. Let $f(u) \geq 0$, supported on $u \asymp 1$, and $|\hat{f}(\xi)| \lesssim_j (|\xi|/T)^j$ for all j . Then*

$$\begin{aligned} J(f) &:= \sup_{0 < M_1, M_2, M_3 < M} \int \left(\sum_{|m_1| \sim M_1, |m_2| \sim M_2, |m_3| \ll M_3} f\left(\frac{m_1 u + m_3}{m_2}\right) \right)^2 du \\ &\lesssim M^6 \left(\int f(u) du \right)^2 + M^4 \int f(u)^2 du. \end{aligned}$$

This is Proposition 9.1 in [3]. This improves the bound on S_3 to

$$S_3 \lesssim T^2 |W|^{3/2} + TN |W|^{1/2} E(W)^{1/2}.$$

This gives an improvement from the previous bound for the case with high energy and $N < T^{1-\delta}$.

Remark: The proof to Lemma 3.5 does not use probability. Instead, it applies Plancherel's theorem on $\sum_{m_1, m_2, m_3} f$ and bounds in the Fourier domain. At low frequencies, this can be bounded by the L_1 norm of f . At high frequencies, the Fourier transform of f decays rapidly. Finally, at mid frequencies, the integral relates to

$$(M^4 \int f^2 du)^{1/2} J(f)^{1/2},$$

by Cauchy Schwarz and a change of variables to decouple m_1 and m_2 , providing the required bound by backward induction.

8. Bound on $E(W)$

Finally, we give an orthogonal bound on the energy of the set W . The idea is that if $|t_1 + t_2 - t_3 - t_4|$ is small, then we can approximate

$$D_N(t_4) \approx D_N(t_1 + t_2 - t_3).$$

This is made precise by applying a smoothing of D_N over a width of $\lesssim 1$. Therefore, since the choice of t_4 is fixed by the choice of t_1, t_2, t_3 , we have

$$E(W) V^2 \leq \sum_{|t_1 - t_2 - t_3 - t_4| \lesssim 1} |D_N(t_4)|^2 \approx \sum_{|t_1 - t_2 - t_3 - t_4| \lesssim 1} |D_N(t_1 + t_2 - t_3)|^2 \leq \sum_{t_1, t_2, t_3 \in W} |D_N(t_1 + t_2 - t_3)|^2.$$

Now we can expand $|D_N(t_1 + t_2 - t_3)|^2$ to get

$$\begin{aligned} \sum_{t_1, t_2, t_3 \in W} |D_N(t_1 + t_2 - t_3)|^2 &= \sum_{t_1, t_2, t_3 \in W} \sum_{n_1, n_2 \sim N} b_{n_1} \bar{b}_{n_2} \left(\frac{n_1}{n_2}\right)^{i(t_1 + t_2 - t_3)} \\ &= \sum_{n_1, n_2 \sim N} b_{n_1} \bar{b}_{n_2} \sum_{t_1, t_2, t_3 \in W} \left(\frac{n_1}{n_2}\right)^{i(t_1 + t_2 - t_3)} \\ &\leq \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}\right) R\left(\frac{n_1}{n_2}\right) R\left(\frac{n_2}{n_1}\right) \right| \\ &\leq \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}\right) \right|^3. \end{aligned}$$

Now we can apply the trivial bound $|R| \leq |W|$ to get that

$$E(W) \lesssim V^{-2} |W| \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}\right) \right|^2.$$

This is in turn bounded by Heath-Brown's result as

$$\begin{aligned} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}\right) \right|^2 &= \sum_{n_1, n_2 \sim N} \sum_{t_1, t_2 \in W} \left(\frac{n_1}{n_2}\right)^{i(t_1 - t_2)} \\ &= \sum_{t_1, t_2 \in W} \left| \sum_{n \sim N} n^{i(t_1 - t_2)} \right|^2 \end{aligned}$$

$$\lesssim |W|N^2 + |W|^2N + |W|^{5/4}T^{1/2}N.$$

This is enough to give an improvement on Ingham-Huxley's result, but can be further improved using Cauchy Schwartz on the third moment

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}\right) \right|^3 \leq \left(\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}\right) \right|^2 \right)^{1/2} \left(\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}\right) \right|^4 \right)^{1/2}.$$

The fourth moment can be reduced back to the second moment by taking representative classes of $[t_1 - t_2]$, thus can also be bounded using Heath-Brown's result.

Chapter 4

Towards a Hybrid Zero Density Result

We would like to generalize Guth and Maynard's result to L -functions. Specifically, let χ be a Dirichlet character. we are interested in the the zeros of the function defined by

$$L(s, \chi) := \sum_n \frac{\chi(n)}{n^{-s}}$$

on $\Re(s) > 1$ and its analytic continuation on the whole complex plane. The zeta function is a special case of an L -function with the Dirichlet character 1 everywhere. The structure of the arguments for analytic continuation of an L -function, its line of symmetry along $\Re(s) = 1/2$, and the locations of zeros are very similar to that of the zeta function. This motivates the Generalized Riemann Hypothesis.

Conjecture 4.1 (Generalized Riemann Hypothesis). *The Generalized Riemann Hypothesis asserts that on the critical strip,*

$$L(s, \chi) = 0 \implies \Re(s) = \frac{1}{2},$$

for any Dirichlet character.

The Generalized Riemann Hypothesis leads to even stronger for primes in short intervals. Namely, fix an integer q , we have that

$$\sum_{\substack{n \leq N \\ n \equiv a \pmod q}} \Lambda(n) = \begin{cases} \frac{1}{\phi(q)} N + O(x^{2+o(1)}), & \text{if } \gcd(a, q) = 1 \\ o(n), & \text{otherwise.} \end{cases}$$

This means that not only that the Prime Number Theorem holds in intervals of $x^{2+\epsilon}$, the distribution of primes in each of the residual classes (coprime to q) are uniform at this scale too. Noticing that we can modify Huxley's proof with

$$M_{x, \chi} = \sum_{n \leq x} \chi(n) \mu(n) n^{-s},$$

we have

$$L(s, \chi) M_{x, \chi} = \sum_n a_n \chi(n) \mu(n) n^{-s}.$$

Thus, we can reproduce a similar proof on the zero density of L -functions.

Definition 4.2 (Zero Density for L -functions). *Let $N(\sigma, \chi, T)$ denote the number of zeros of the L -function $L(-, \chi)$ with real part greater than σ and imaginary part between $-T$ and T . That is*

$$N(\sigma, \chi, T) := \#\{\rho = \beta + i\gamma \mid \beta \geq \sigma, |\gamma| \leq T\}.$$

For backwards compatibility with our previous definition, we take $N(\sigma, T) := N(\sigma, 1, T)$.

The hybrid analogs of the zero density bounds of Ingham and Huxley are known.

Theorem 4.3 (Hybrid Ingham bound for zero density). *Let $1/2 \leq \sigma \leq 3/4$. We have*

$$\sum_{\chi^*} N(\sigma, \chi^*, t) \lesssim (qT)^{\frac{3(1-\sigma)}{2-\sigma}},$$

where \sum_{χ^*} sums over all the primitive characters χ^* of modulus q .

Theorem 4.4 (Hybrid Huxley bound for zero density). *Let $3/4 \leq \sigma \leq 1$. We have*

$$\sum_{\chi^*} N(\sigma, \chi^*, t) \lesssim (qT)^{\frac{3(1-\sigma)}{3\sigma-1}},$$

where \sum_{χ^*} sums over all the primitive characters χ^* of modulus q .

The method for detecting zeros is very similar to Huxley's proof above with the slight change in definition of $M_{x,\chi}$. This argument then reduces to bounding the number of times large values of Dirichlet polynomials can occur. Therefore we want a result in the form:

Let $\mathcal{S} = \{(t_j, \chi_j)\}$ be a set such that each χ_j is a primitive Dirichlet character of modulus q , and $|t_j - t_k| \geq 1$ if $j \neq k$ and $\chi_j = \chi_k$. (That is, the t 's are 1-separated if the characters are the same.) Let $|b_n| \leq 1$ be a sequence of numbers indexed in n , and suppose also that

$$\left| \sum_{n \sim N} b_n \chi_j(n) n^{it_j} \right| > V.$$

We want to find a bound on $|\mathcal{S}|$.

Our result is as follows:

Theorem 4.5. *To be determined \odot .*

The idea of the proof is similar to Guth and Maynard's proof. We can define a $|\mathcal{S} \times N|$ matrix M with entries

$$M_{t_j, \chi_j, n} = \chi_j(n) n^{it_j}$$

for $(t_j, \chi_j) \in \mathcal{S}$ and $n \sim N$, and bound its operator norm in the exact same way: taking it to the M^*M to the third power and calculating its trace. The Dirichlet characters are not nice to handle when extended to a function $\mathbb{R} \rightarrow \mathbb{C}$, so we instead break the sum into q summations across each residue class mod q , and apply Poisson summation on each piece of the sum. This gives us

$$\begin{aligned} \text{tr}((M^*M)^3) &= \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \frac{N^3}{q^3} \sum_{m \in \mathbb{Z}^3} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e\left(\frac{-x \cdot m}{q}\right) \\ &\quad \times \hat{h}_{t_1-t_3}\left(\frac{Nm_1}{q}\right) \hat{h}_{t_2-t_1}\left(\frac{Nm_2}{q}\right) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right), \end{aligned}$$

where $h_t(x) := \omega(u)^2 x^{it}$ has the same definition, thus its fourier transform has the same properties in decay. Similarly, we find that when we break the sum in \mathbb{Z}^3 into S_0 to S_3 in the same way, S_0 gives the main term, S_1 is negligible, and S_2 can be bounded by Heath-Brown's theorem. For the S_3 bound, we redefine

$$R(v, n_1, n_2) := \sum_{(t, \chi) \in \mathcal{S}} \chi(n_1) \bar{\chi}(n_2) v^{it}.$$

This additional structure in χ may look complicated when taking the L_2 or L_4 norm of R in $v \asymp 1$, but this cancels out when taking

$$\sum_{n_1 \in \mathbb{Z}/q\mathbb{Z}} R(v, n_1, n_2)^2 = \sum_{n_1 \in \mathbb{Z}/q\mathbb{Z}} \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} \chi_1(n_1) \bar{\chi}_2(n_1) \bar{\chi}_1(n_2) \chi_2(n_2) v^{i(t_1-t_2)}.$$

By the orthogonality of Dirichlet characters, the sum in n_1 vanishes except when $\chi_1 = \chi_2$, in which case (assuming $\gcd(n_2, q) = 1$) we can reduce

$$\sum_{n_1 \in \mathbb{Z}/q\mathbb{Z}} R(v, n_1, n_2)^2 = \phi(q) \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ \chi_1 = \chi_2}} v^{i(t_1 - t_2)}.$$

When $\chi_1 = \chi_2$, we have $t_1 = t_2$ or they are T^ϵ separated, giving us decay in the calculation of the second moment of R to be $\phi(q)|\mathcal{S}|$. Similarly, we see the fourth power of R cancels in the sum

$$\sum_{n_1 \in \mathbb{Z}/q\mathbb{Z}} R(v, n_1, n_2)^4 = \sum_{n_1 \in \mathbb{Z}/q\mathbb{Z}} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S}}} \chi_1 \chi_2 \bar{\chi}_3 \bar{\chi}_4(n_1) \bar{\chi}_1 \bar{\chi}_2 \chi_3 \chi_4(n_2) v^{i(t_1 + t_2 - t_3 - t_4)}.$$

Only terms where $\chi_1 \chi_2 = \chi_3 \chi_4$ can have non-zero contribution, giving us a natural definition for the energy of the set to be

$$E(\mathcal{S}) := \#\{(t_1, \chi_1), (t_2, \chi_2), (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \mid \chi_1 \chi_2 = \chi_3 \chi_4, |t_1 + t_2 - t_3 - t_4| \lesssim 1\}.$$

This in turn can be bounded by a third moment of R :

$$E(\mathcal{S}) \lesssim N^{-2\sigma} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^3.$$

This expression is then bounded by Heath-Brown's theorem.

4.1 Setup and Reduction of Theorem

Lemma 4.6. *Let $\mathcal{S} = \{(t_j, \chi_j)\}$ be a set such that each χ_j is a primitive Dirichlet character of modulus q , and $|t_j - t_k| \geq T^\epsilon$ if $j \neq k$ and $\chi_j = \chi_k$. Let $|b_n| \leq 1$ be a sequence of numbers indexed in n , ω be a smooth bump function that equals 1 on $[6/5, 9/5]$ and has support in $[1, 2]$ (thus $\omega^{(A)} \ll_A 1$ for all A). Let $V = N^\sigma$, where $\sigma \in [\text{placeholder}]$, and $N = qT^\alpha$, where $\alpha \in [\text{placeholder}]$, and $q^{1+\epsilon} \ll N, T$. Suppose also that*

$$|D_N(t_j, \chi_j)| := \left| \sum_{n \sim N} \omega\left(\frac{n}{N}\right) b_n \chi_j(n) n^{it_j} \right| > V.$$

for all $(t_j, \chi_j) \in \mathcal{S}$. Then

$$|\mathcal{S}| \lesssim \odot.$$

Proof of main theorem from Lemma 4.6. We split

$$\sum_{n \sim N} b_n \chi_j(n) n^{it_j} = \sum_{N \leq n < 6N/5} b_n \chi_j(n) n^{it_j} + \sum_{6N/5 \leq n < 9N/5} b_n \chi_j(n) n^{it_j} + \sum_{9N/5 \leq n < 2N} b_n \chi_j(n) n^{it_j}.$$

So that if

$$\left| \sum_{n \sim N} b_n \chi_j(n) n^{it_j} \right| > V,$$

then at least one of the three summations in the right has magnitude at least $V/3$. But then each of these sums can be written as dirichlet sums in the form of the lemma:

$$\begin{aligned} \sum_{N \leq n < 6N/5} b_n \chi_j(n) n^{it_j} &= \sum_{N \leq n < 6N/5} \omega\left(\frac{n}{11N/15}\right) b_n \chi_j(n) n^{it_j}, \\ \sum_{6N/5 \leq n < 9N/5} b_n \chi_j(n) n^{it_j} &= \sum_{6N/5 \leq n < 9N/5} \omega\left(\frac{n}{N}\right) b_n \chi_j(n) n^{it_j}, \\ \sum_{9N/5 \leq n < 2N} b_n \chi_j(n) n^{it_j} &= \sum_{9N/5 \leq n < 2N} \omega\left(\frac{n}{19N/15}\right) b_n \chi_j(n) n^{it_j}. \end{aligned}$$

Applying the lemma on each of these three pieces and summing the three bounds gives the same bound for $\sum_{n \sim N} b_n \chi_j(n) n^{it_j}$ up to a constant factor. \square

4.2 The matrix M and its trace expansion

We define M a $|\mathcal{S}| \times N$ matrix with entries

$$M_{(t_j, \chi_j), n} = \omega\left(\frac{n}{N}\right) \chi_j(n) n^{it_j}$$

for $(t_j, \chi_j) \in \mathcal{S}$ and $n \sim N$. Thus by the same reasoning that $(M\vec{b})_j = D_N(t_j, \chi_j)$, we want to bound the size of \mathcal{S} by trace of the matrix

$$\text{tr}((M^*M)^3).$$

Proposition 4.7. *Let*

$$\begin{aligned} I_m := \frac{N^3}{q^3} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e\left(\frac{-x \cdot m}{q}\right) \\ \times \hat{h}_{t_1-t_3}\left(\frac{Nm_1}{q}\right) \hat{h}_{t_2-t_1}\left(\frac{Nm_2}{q}\right) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right). \end{aligned}$$

We have

$$|\mathcal{S}| \lesssim \frac{\phi(q)}{q} N^2 V^{-2} + NV^{-2} \left(\sum_{m \in \mathbb{Z}^3 - \{0\}} I_m \right)^{1/3}.$$

Lemma 4.8 (Explicit Expression of Traces). *Let*

$$P(n, (t_1, \chi_1), (t_2, \chi_2)) := \omega\left(\frac{n}{N}\right)^2 \left(\frac{n}{N}\right)^{i(t_2-t_1)} \chi_2 \bar{\chi}_1(n).$$

We have

$$\begin{aligned} \text{tr}(M^*M) &= |\mathcal{S}| \sum_{n \sim N, \gcd(n, q)=1} \omega\left(\frac{n}{N}\right)^2, \\ \text{tr}((M^*M)^3) &= \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \sum_{n_1, n_2, n_3 \sim N} P(n_1, (t_1, \chi_1), (t_3, \chi_3)) P(n_2, (t_2, \chi_2), (t_1, \chi_1)) P(n_3, (t_3, \chi_3), (t_2, \chi_2)). \end{aligned}$$

Proof. We compute the traces of MM^* and $(MM^*)^3$ instead, as this makes the calculations cleaner. We see that

$$(MM^*)_{(t_j, \chi_j), (t_k, \chi_k)} = \sum_{n \sim N} \omega\left(\frac{n}{N}\right)^2 n^{i(t_k-t_j)} \bar{\chi}_j \chi_k(n) = \sum_{n \sim N} P(n, (t_k, \chi_k), (t_j, \chi_j)) N^{i(t_k-t_j)},$$

so that

$$\begin{aligned} \text{tr}(MM^*) &= \sum_{(t_j, \chi_j)} \sum_{n \sim N} P(n, (t_j, \chi_j), (t_j, \chi_j)) \\ &= |\mathcal{S}| \sum_{n \sim N} |\chi_j(n)| \omega\left(\frac{n}{N}\right)^2. \end{aligned}$$

For the third power, we have

$$(MM^*)_{(t_j, \chi_j), (t_k, \chi_k)}^3 = \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} (MM^*)_{(t_j, \chi_j), (t_1, \chi_1)} (MM^*)_{(t_1, \chi_1), (t_2, \chi_2)} (MM^*)_{(t_2, \chi_2), (t_k, \chi_k)},$$

so that the trace is given by

$$\begin{aligned} & \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} (MM^*)_{(t_3, \chi_3), (t_1, \chi_1)} (MM^*)_{(t_1, \chi_1), (t_2, \chi_2)} (MM^*)_{(t_2, \chi_2), (t_3, \chi_3)} \\ &= \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \sum_{n_1, n_2, n_3 \sim N} P(n_1, (t_1, \chi_1), (t_3, \chi_3)) P(n_2, (t_2, \chi_2), (t_1, \chi_1)) P(n_3, (t_3, \chi_3), (t_2, \chi_2)). \end{aligned}$$

□

We would like to apply Poisson summation directly to P in n_1, n_2, n_3 , respectively. However, we do not have a good way to express the Dirichlet character $\chi_j \bar{\chi}_k$ as a C^∞ function. To get around this, we just split the sum in n into q pieces.

Lemma 4.9 (Poisson Summation with Periodic Arithmetic Function). *Let $f : \mathbb{R} \rightarrow \mathbb{C}$ be Schwartz, and $g : \mathbb{N} \rightarrow \mathbb{C}$ be an arithmetic with period q . Then*

$$\sum_n g(n) f(n) = \frac{1}{q} \sum_{\xi} \sum_{x \bmod q} g(x) e\left(\frac{-x\xi}{q}\right) \hat{f}\left(\frac{\xi}{q}\right).$$

Proof. By absolute convergence, we have

$$\sum_n g(n) f(n) = \sum_n \sum_{x \bmod q} g(qn + x) f(qn + x) = \sum_{x \bmod q} g(x) \sum_n f(qn + x).$$

Applying Poisson summation to the last expression in n gives

$$\frac{1}{q} \sum_{x \bmod q} g(x) \sum_{\xi} e\left(\frac{-x\xi}{q}\right) \hat{f}\left(\frac{\xi}{q}\right).$$

□

Corollary 4.10 (Poisson summation of Trace). *Let $h_t(u) := \omega(u)^2 u^{it}$, Then*

$$\begin{aligned} \text{tr}(M^* M) &= |S| \frac{N}{q} \sum_m \sum_{x \in \mathbb{Z}/q\mathbb{Z}} e\left(\frac{-xm}{q}\right) \hat{h}_0\left(\frac{Nm}{q}\right) \\ \text{tr}((M^* M)^3) &= \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \frac{N^3}{q^3} \sum_{m \in \mathbb{Z}^3} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e\left(\frac{-x \cdot m}{q}\right) \\ &\quad \times \hat{h}_{t_1-t_3}\left(\frac{Nm_1}{q}\right) \hat{h}_{t_2-t_1}\left(\frac{Nm_2}{q}\right) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right). \end{aligned}$$

In the trace of $(M^* M)^3$, we split the sum in $m := (m_1, m_2, m_3)$ according to the number of non-zero entries into four parts (same as Guth Maynard Sketch above) $S_0 + S_1 + S_2 + S_3$, where S_j runs over the values of m with exactly j non-zero entries.

Lemma 4.11 (Isolation of main term). *We have*

$$\begin{aligned} \text{tr}(M^* M) &= \frac{|S|N\phi(q)}{q} \|\omega\|_{L_2}^2 + O(T^{-100}), \\ S_0 &= \frac{|S|N^3\phi(q)^3}{q^3} \|\omega\|_{L_2}^6 + O(T^{-100}). \end{aligned}$$

Proof. By Non-Stationary Phase, we have rapid decay of $h_0(\xi)$, so we can only consider the terms with $m = 0$ in the sum for $\text{tr}(M^* M)$ at a cost of $O(T^{-100})$. This $m = 0$ term evaluates to

$$\frac{|S|N}{q} \sum_{x \in \mathbb{Z}/q\mathbb{Z}} e(0) \hat{h}_0(0) = \frac{|S|N\phi(q)}{q} \|\omega\|_{L_2}^2.$$

For S_0 , we have

$$S_0 = \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \frac{N^3}{q^3} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2}(0).$$

By the orthogonality of characters (as representations of $(\mathbb{Z}/q\mathbb{Z})^\times$), only the terms with $\chi_1 = \chi_2 = \chi_3$ can have non-zero contribution to the sum. But when $\chi_1 = \chi_2 = \chi_3$, $|t_i - t_j| = 0$ or $|t_i - t_j| \geq T^\epsilon$. In the second case, we can apply Non-Stationary Phase to get rapid decay in $\hat{h}_{t_i-t_j}(0)$. Therefore

$$S_0 = \sum_{(t, \chi) \in \mathcal{S}} \frac{N^3}{q^3} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \hat{h}_0(0)^3 + O(T^{-100}) = \frac{|\mathcal{S}| N^3 \phi(q)^3}{q^3} \|\omega\|_{L_2}^6 + O(T^{-100}).$$

□

Proof of Proposition 4.7. We note that the inequality in equation 3.1 applies in this case, and apply Lemma 3.4 and substitute the values we have obtained. □

4.3 S_1 bound

Proposition 4.12. $S_1 = O(\epsilon(T^{-10}))$.

Proof. Recall that

$$S_1 = \sum_{\substack{m_1, m_2, m_3 \in \mathbb{Z}, \\ \#\{m_j \mid m_j \neq 0\} = 1}} I_m.$$

By symmetry, we sum I_m across all $m = (0, 0, m_3 \neq 0)$ at a cost of a factor of 3. In this case,

$$\begin{aligned} I_{(0,0,m_3)} &= \frac{N^3}{q^3} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e\left(\frac{-x_3 m_3}{q}\right) \\ &\quad \times \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right) \end{aligned}$$

By the orthogonality of characters, this expression vanishes when $\chi_1 \neq \chi_2$ (consider summation in x_2) or $\chi_2 \neq \chi_3$ (summation in x_1). Therefore, we can further restrict our summation in \mathcal{S} to be over terms with $\chi_1 = \chi_2 = \chi_3$ to get

$$\begin{aligned} I_m &= \frac{N^3}{q^3} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2 = \chi_1), \\ (t_3, \chi_3 = \chi_1) \in \mathcal{S}}} \phi(q)^2 \sum_{x_3 \in (\mathbb{Z}/q\mathbb{Z})^\times} e\left(\frac{-x_3 m_3}{q}\right) \\ &\quad \times \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right) \\ &= O\left(\frac{N^3 \phi(q)^3}{q^3}\right) \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2 = \chi_1), \\ (t_3, \chi_3 = \chi_1) \in \mathcal{S}}} \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right) \end{aligned}$$

So we trivially bound S_1 by

$$|S_1| \ll \frac{N^3}{q^3} \phi(q)^3 \sum_{m_3 \neq 0} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2 = \chi_1), \\ (t_3, \chi_3 = \chi_1) \in \mathcal{S}}} \left| \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right) \right|$$

On the right hand side, we split the sum into three parts

$$\frac{N^3}{q^3} \phi(q)^3 (S_{1,1} + S_{1,2} + S_{1,3}),$$

where

$$\begin{aligned} S_{1,1} &= \sum_{|m_3| > qT^{1+\epsilon}/N} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2 = \chi_1), \\ (t_3, \chi_3 = \chi_1) \in \mathcal{S}}} \left| \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2} \left(\frac{Nm_3}{q} \right) \right|, \\ S_{1,2} &= \sum_{|m_3| \leq qT^{1+\epsilon}/N} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2 = \chi_1), \\ (t_3, \chi_3 = \chi_1) \in \mathcal{S}, \\ t_1 \neq t_2 \text{ or } t_1 \neq t_3}} \left| \hat{h}_{t_1-t_3}(0) \hat{h}_{t_2-t_1}(0) \hat{h}_{t_3-t_2} \left(\frac{Nm_3}{q} \right) \right|, \\ S_{1,3} &= \sum_{|m_3| \leq qT^{1+\epsilon}/N} \sum_{(t, \chi) \in \mathcal{S}} \left| \hat{h}_0(0) \hat{h}_0(0) \hat{h}_0 \left(\frac{Nm_3}{q} \right) \right|. \end{aligned}$$

We now apply Non-Stationary Phase to \hat{h} . In $S_{1,1}$, we consider the terms with $|m_3| > qT^{1+\epsilon}/N$, we have decay in

$$\hat{h}_{t_3-t_2} \ll_A \left(\frac{Nm_3}{q} \right) (1 + |t_3 - t_2|)^A \left(\frac{N|m_3|}{q} \right)^{-A} \ll T^A (T^{1+\epsilon})^{-A} \left(\frac{N|m_3|}{qT^{1+\epsilon}} \right)^{-A}.$$

Therefore, we trivially bound $\hat{h}_t \xi \ll 1$ to obtain a bound of $O_\epsilon(T^{-100})$ for the sum across $|m_3| > qT^{1+\epsilon}/N$. Similarly, for $S_{1,2}$ with terms consisting $t_1 \neq t_2$ or $t_1 \neq t_3$, they will be T^ϵ apart, so $\hat{h}_{t_2-t_1}(0)$ or $\hat{h}_{t_1-t_3}(0)$ can be bounded by $O_\epsilon(T^{-100})$.

The final terms to bound are when $t_1 = t_2 = t_3$ in $S_{1,3}$, in which case

$$\left| \hat{h}_{t_3-t_2} \left(\frac{Nm_3}{q} \right) \right| \ll_A \left(\frac{q}{N} \right)^A \ll_\epsilon T^{-100}.$$

Combined, the contribution of S_1 is $O_\epsilon(T^{-10})$. □

4.4 S_2 bound

Proposition 4.13. *We have for any integer k ,*

$$S_2 \lesssim_k |\mathcal{S}|^2 N + |\mathcal{S}|^{2-1/k} N^2 + |\mathcal{S}|^2 N^2 \left(\frac{(qT)^{1/2}}{|\mathcal{S}^{3/4}|} \right)^{1/k}.$$

Lemma 4.14. *We have*

$$S_2 = 3 \frac{N^3}{q^3} \phi(q) \hat{h}_0(0) \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S}}} \left| \sum_{m \neq 0} \sum_{x \in \mathbb{Z}/q\mathbb{Z}} \chi_1 \bar{\chi}_2(x) e \left(\frac{-mx}{q} \right) \hat{h}_{t_1-t_2} \left(\frac{Nm}{q} \right) \right|^2 + O(T^{-10}).$$

Proof. We write by symmetry

$$S_2 = 3 \frac{N^3}{q^3} \sum_{m_1, m_2 \neq 0} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e \left(\frac{-x_1 m_1 - x_2 m_2}{q} \right)$$

$$\times \hat{h}_{t_1-t_3} \left(\frac{Nm_1}{q} \right) \hat{h}_{t_2-t_1} \left(\frac{Nm_2}{q} \right) \hat{h}_{t_3-t_2}(0)$$

Removing zero contributions from $\chi_2 \neq \chi_3$ by orthogonality, we have

$$\begin{aligned} &= 3 \frac{N^3}{q^3} \phi(q) \sum_{m_1, m_2 \neq 0} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3 = \chi_2) \in \mathcal{S}}} \sum_{x_1, x_2 \in \mathbb{Z}/q\mathbb{Z}} \chi_1 \bar{\chi}_2(x_1) \chi_2 \bar{\chi}_1(x_2) e \left(\frac{-x_1 m_1 - x_2 m_2}{q} \right) \\ &\quad \times \hat{h}_{t_1-t_3} \left(\frac{Nm_1}{q} \right) \hat{h}_{t_2-t_1} \left(\frac{Nm_2}{q} \right) \hat{h}_{t_3-t_2}(0) \end{aligned}$$

Here, we can isolate contributions from the terms where $t_2 \neq t_3$ (hence since $\chi_2 = \chi_3$, are T^ϵ separated) to be $O(T^{-10})$. For the other terms, we can write

$$\hat{h}_t(\xi) = \overline{\hat{h}_{-t}(-\xi)}$$

to get

$$S_2 = 3 \frac{N^3}{q^3} \phi(q) \hat{h}_0(0) \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S}}} \left| \sum_{m \neq 0} \sum_{x \in \mathbb{Z}/q\mathbb{Z}} \chi_1 \bar{\chi}_2(x) e \left(\frac{-mx}{q} \right) \hat{h}_{t_1-t_2} \left(\frac{Nm}{q} \right) \right|^2 + O(T^{-10}).$$

□

Proof of Proposition 4.13. By the principle of non-stationary phase the terms where $(t_1, \chi_1) = (t_2, \chi_2)$ contribute $O(T^{-10})$. If $\chi_1 \neq \chi_2$, then we can apply the orthogonality of characters to extend the summation in m to include $m = 0$ too. Lastly, if $\chi_1 = \chi_2$ and $t_1 \neq t_2$, we add the negligible term corresponding to $m = 0$, as $\hat{h}_{t_1-t_2}(0)$ is negligible. Therefore, we have

$$\begin{aligned} S_2 &\ll \frac{N^3}{q^3} \phi(q) \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S} \\ (t_1, \chi_1) \neq (t_2, \chi_2)}} \left| \sum_{m \neq 0} \sum_{x \in \mathbb{Z}/q\mathbb{Z}} \chi_1 \bar{\chi}_2(x) e \left(\frac{-mx}{q} \right) \hat{h}_{t_1-t_2} \left(\frac{Nm}{q} \right) \right|^2 + O(T^{-10}) \\ &\stackrel{\text{Poisson}}{=} \frac{N}{q} \phi(q) \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S} \\ (t_1, \chi_1) \neq (t_2, \chi_2)}} \left| \sum_{n \sim N} \chi_1 \bar{\chi}_2(n) \omega \left(\frac{n}{N} \right)^2 \left(\frac{n}{N} \right)^{i(t_1-t_2)} \right|^2 + O(T^{-10}) \\ &= \frac{N}{q} \phi(q) \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S} \\ (t_1, \chi_1) \neq (t_2, \chi_2)}} \left| \sum_{n \sim N} \chi_1 \bar{\chi}_2(n) \omega \left(\frac{n}{N} \right)^2 n^{i(t_1-t_2)} \right|^2 + O(T^{-10}) \\ &\leq \frac{N}{q} \phi(q) \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S}}} \left| \sum_{n \sim N} \chi_1 \bar{\chi}_2(n) \omega \left(\frac{n}{N} \right)^2 n^{i(t_1-t_2)} \right|^2 + O(T^{-10}). \end{aligned}$$

Before we apply Heath-Brown's theorem, we use Hölder's inequality to get

$$\begin{aligned} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S}}} \left| \sum_{n \sim N} \chi_1 \bar{\chi}_2(n) \omega \left(\frac{n}{N} \right)^2 n^{i(t_1-t_2)} \right|^2 &\leq \left(\sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S}}} 1 \right)^{(k-1)/k} \left(\sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S}}} \left| \sum_{n \sim N} \chi_1 \bar{\chi}_2(n) \omega \left(\frac{n}{N} \right)^2 n^{i(t_1-t_2)} \right|^{2k} \right)^{1/k} \\ &= |S|^{2-2/k} \left(\sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2) \in \mathcal{S}}} \left| \sum_{n \asymp_k N^k} O(d(n)) \chi_1 \bar{\chi}_2(n) n^{i(t_1-t_2)} \right|^{2k} \right)^{1/k}. \end{aligned}$$

As the divisor is bounded by $d(n) = N^{o(1)}$, we apply Heath-Brown's theorem to bound the second term by

$$\lesssim_k (|S|^2 N^k + |S| N^{2k} + |S|^{5/4} (qT)^{1/2} N^k)^{1/k} \ll_k |S|^{2k} N + |S|^{1/k} N^2 + |S|^{5/(4k)} (qT)^{1/(2k)} N.$$

Therefore, combined with the previous bound on S_2 , we have

$$S_2 \lesssim \frac{N}{q} \phi(q) |S|^{2-2/k} (|S|^{2k} N + |S|^{1/k} N^2 + |S|^{5/(4k)} (qT)^{1/(2k)} N)$$

which gives the proposition upon simplification. \square

4.5 S_3 bound

Proposition 4.15 (Preliminary bound on S_3). *We have*

$$S_3 \lesssim \left(\frac{\phi(q)}{q} \right)^2 (qT)^2 E(S)^{1/2} |S|^{1/2}.$$

Recall that

$$\begin{aligned} I_m := \frac{N^3}{q^3} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e\left(\frac{-x \cdot m}{q}\right) \\ \times \hat{h}_{t_1-t_3}\left(\frac{Nm_1}{q}\right) \hat{h}_{t_2-t_1}\left(\frac{Nm_2}{q}\right) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right). \end{aligned}$$

By non-stationary phase, I_m is negligible for the terms $qT/N \lesssim |m|$, so

$$S_3 = \sum_{0 < |m_1|, |m_2|, |m_3| \lesssim qT/N} I_m + O(T^{-100}). \quad (4.1)$$

Furthermore, by symmetry in m_1, m_2, m_3 , we can consider the terms $|m_1| \leq |m_2| \leq |m_3|$ at a cost of a factor of 6. We first consider the triple summation in \mathbb{Z}/q . Define

$$A_{m, \chi_1, \chi_2, \chi_3} := \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e\left(\frac{-x \cdot m}{q}\right),$$

which is the inner summation in I_m . Notice that $\chi(0) = 0$, so we can define the summation in A to run over $(\mathbb{Z}/q\mathbb{Z})^\times$ to get

$$A_{m, \chi_1, \chi_2, \chi_3} = \sum_{x \in ((\mathbb{Z}/q\mathbb{Z})^\times)^3} \chi_1 \bar{\chi}_3(x_1) \chi_2 \bar{\chi}_1(x_2) \chi_3 \bar{\chi}_2(x_3) e\left(\frac{-x \cdot m}{q}\right)$$

We now make the substitution $y_1 = x_1 x_3^{-1}, y_2 = x_2 x_3^{-1} \pmod q$ for the summation over x . We thus rewrite the sum over x as

$$\begin{aligned} & \sum_{y_1, y_2, x_3 \in (\mathbb{Z}/q\mathbb{Z})^\times} \chi_1(y_1 y_2^{-1}) \chi_2(y_2) \chi_3(y_1^{-1}) e\left(\frac{-(y_1 m_1 + y_2 m_2 + m_3) x_3}{q}\right) \\ &= \sum_{y_1, y_2 \in (\mathbb{Z}/q\mathbb{Z})^\times} \chi_1(y_1) \bar{\chi}_1(y_2) \chi_2(y_2) \bar{\chi}_3(y_1) \sum_{x_3 \in (\mathbb{Z}/q\mathbb{Z})^\times} e\left(\frac{-(y_1 m_1 + y_2 m_2 + m_3) x_3}{q}\right) \end{aligned}$$

Now we can apply Möbius inversion on the summation in x_3 to get

$$\sum_{x_3 \in (\mathbb{Z}/q\mathbb{Z})^\times} e\left(\frac{-(y_1 m_1 + y_2 m_2 + m_3) x_3}{q}\right) = \sum_{q_0|q} \mu\left(\frac{q}{q_0}\right) \sum_{\tilde{x}_3 \in \mathbb{Z}/q_0} e\left(\frac{-(y_1 m_1 + y_2 m_2 + m_3) \tilde{x}_3}{q_0}\right)$$

$$= \sum_{q_0|q} \mu\left(\frac{q}{q_0}\right) q_0 \mathbb{I}_{q_0|(y_1 m_1 + y_2 m_2 + m_3)}.$$

With this in mind, we break $I_m = \sum_{q_0|q} \mu(q/q_0) I_{m,q_0}$,

$$\begin{aligned} I_{m,q_0} &:= \frac{N^3 q_0}{q^2} \sum_{\substack{(t_1, \chi_1), \\ (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \sum_{\substack{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z} \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \chi_1(y_1) \bar{\chi}_1(y_2) \chi_2(y_2) \bar{\chi}_3(y_1) \\ &\quad \times \hat{h}_{t_1-t_3}\left(\frac{Nm_1}{q}\right) \hat{h}_{t_2-t_1}\left(\frac{Nm_2}{q}\right) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right). \end{aligned}$$

Proposition 4.16 (Divisor reduction of S_3). *We have*

$$S_3 \lesssim \sup_{q_0|q} \sum_{\substack{0 < |m_1|, |m_2|, \\ |m_3| \lesssim qT/N}} I_{m,q_0}.$$

Proof. We split the sum in I_m to be across I_{m,q_0} for each divisor of q . The divisor function grows slower than any power of q , so gives the proposition. \square

We then consider the subproduct in I_{m,q_0} :

$$\hat{h}_{t_1-t_3}\left(\frac{Nm_1}{q}\right) \hat{h}_{t_2-t_1}\left(\frac{Nm_2}{q}\right) \hat{h}_{t_3-t_2}\left(\frac{Nm_3}{q}\right).$$

Expanding the Fourier transform as an integral, this expression equals

$$\begin{aligned} &\int_{\mathbb{R}^3} \tilde{\omega}(\mathbf{u}) u_1^{i(t_1-t_3)} u_2^{i(t_2-t_1)} u_3^{i(t_3-t_2)} e\left(\frac{-N\mathbf{m} \cdot \mathbf{u}}{q}\right) d\mathbf{u} \\ &= \int_{\mathbb{R}^3} \tilde{\omega}(\mathbf{u}) \left(\frac{u_1}{u_2}\right)^{it_1} \left(\frac{u_2}{u_3}\right)^{it_2} \left(\frac{u_3}{u_1}\right)^{it_3} e\left(\frac{-N\mathbf{m} \cdot \mathbf{u}}{q}\right) d\mathbf{u} \end{aligned}$$

where $\tilde{\omega}(u_1, u_2, u_3) := \omega(u_1)^2 \omega(u_2)^2 \omega(u_3)^2$ is compactly supported. The observation is that the choice of u_1/u_2 and u_2/u_3 fixes u_3/u_1 , so this triple integral can be rewritten in two variables. We change variables $v_1 = u_1/u_3, v_2 = u_2/u_3$ for the integral, which is well defined on the support of $\tilde{\omega}$. This gives us a Jacobian of u_3^2 and equals

$$\begin{aligned} &\int_{\mathbb{R}^3} \tilde{\omega}(v_1 u_3, v_2 u_3, u_3) \left(\frac{v_1}{v_2}\right)^{it_1} (v_2)^{it_2} \left(\frac{1}{v_1}\right)^{it_3} u_3^2 e\left(\frac{-N(v_1 m_1 + v_2 m_2 + m_3) u_3}{q}\right) dv_1 dv_2 du_3 \\ &= \int_{\mathbb{R}^2} \int_{\mathbb{R}} u_3^2 \tilde{\omega}(v_1 u_3, v_2 u_3, u_3) e\left(\frac{-N(v_1 m_1 + v_2 m_2 + m_3) u_3}{q}\right) du_3 \left(\frac{v_1}{v_2}\right)^{it_1} (v_2)^{it_2} \left(\frac{1}{v_1}\right)^{it_3} dv_1 dv_2. \end{aligned} \tag{4.2}$$

We define

$$\begin{aligned} R(v, n_1, n_2) &:= \sum_{(t, \chi) \in \mathcal{S}} \chi(n_1) \bar{\chi}(n_2) v^{it}, \\ R(v, n) &:= R(v, n, 1). \end{aligned}$$

Therefore,

$$I_{m,q_0} = \frac{N^3 q_0}{q^3} \sum_{\substack{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z} \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \int_{\mathbb{R}^2} \tilde{I}_{u_3}(v_1, v_2) R\left(\frac{v_1}{v_2}, y_1, y_2\right) R(v_2, y_2) R\left(\frac{1}{v_1}, y_1^{-1}\right) dv_1 dv_2,$$

where

$$\tilde{I}_{u_3}(v_1, v_2) := \tilde{I}_{u_3}(v_1, v_2, m) := \int_{\mathbb{R}} u_3^2 \tilde{\omega}(v_1 u_3, v_2 u_3, u_3) e\left(\frac{-N(v_1 m_1 + v_2 m_2 + m_3) u_3}{q}\right) du_3.$$

The innermost integral $\tilde{I}_{u_3}(v_1, v_2)$ has cancellation property. By the principle of non-stationary phase through repeated integration by parts, this integral is $O_{\epsilon, A}(T^{-A})$ for any $|v_1 m_1 + v_2 m_2 + m_3| > qT^\epsilon/N$. Therefore, we can truncate the domain of the integrals in v_1 and v_2 to $|v_1 m_1 + v_2 m_2 + m_3| \lesssim q/N$ with negligible error. On this domain, the innermost integral in u_3 is $O(1)$ by the trivial bound. Moreover, by the compact support of $\tilde{\omega}$ on $[1, 2] \times [1, 2] \times [1, 2]$ the integrand of innermost integral is non-zero only if

$$v_1 u_3, v_2 u_3, u_3 \sim N.$$

Importantly, this requires $1/2 \leq v_1, v_2 \leq 2$, so we can further restrict the outermost integrals to this region. We therefore have:

Proposition 4.17 (Simplification of I_{m, q_0} domain).

$$|I_{m, q_0}| \ll \frac{N^3 q_0}{q^3} \sum_{\substack{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z} \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \int_{\substack{|v_1 m_1 + v_2 m_2 + m_3| \lesssim \frac{q}{N} \\ \frac{1}{2} \leq v_1, v_2 \leq 2}} R\left(\frac{v_1}{v_2}, y_1, y_2\right) R(v_2, y_2) R\left(\frac{1}{v_1}, y_1^{-1}\right) dv_1 dv_2 + O_\epsilon(T^{-100}).$$

Moreover, if $|m_1| \leq |m_2| \leq |m_3|$, $|I_{m, q_0}| = O(T^{-100})$ unless $|m_2| \asymp |m_3|$.

Proof. The first statement is a result of our work so far. The second part of the proposition follows from the integral bounds $|v_1 m_1 + v_2 m_2 + m_3| \lesssim q/N$ and $v_1, v_2 \asymp 1$. When $|m_1| \leq |m_2|$, we have $|v_1 m_1 + v_2 m_2| = O(|m_2|)$. These force $|m_2| \asymp |m_3|$, or else the integral will be negligible as the domain of the integration will be outside the range $|v_1 m_1 + v_2 m_2 + m_3| \lesssim q/N$. \square

When $|m_2| \asymp |m_3|$, the domain of integration can be written as

$$|v_1 m_1 + v_2 m_2 + m_3| \lesssim \frac{q}{N} \implies \left| v_2 - \frac{v_1 m_1 + m_3}{-m_2} \right| \lesssim \frac{q}{|m_2|N} \asymp \frac{q}{|m_3|N}.$$

Thus, if we fix v_1 , the integration in v_2 is in a $q/(|m_3|N)$ -small neighborhood of $\frac{v_1 m_1 + m_3}{-m_2}$. In principle, we can estimate the value of the integral by evaluating at $v_2 = v_1 m_1 + m_3 / -m_2$ and multiplying it by $q/(|m_3|N)$. This is made precise by splitting the sum across m_3 into dyadic intervals M , and smoothing over ranges of $q/(MN)$.

Let $\tilde{\phi}$ be a smooth bump function such that equals $\tilde{\phi} = 1$ on $|x| \lesssim 1$ and is supported in $|x| \lesssim 1$ (with a larger constant), so that $\|\tilde{\phi}^{(j)}\| \lesssim_j 1$ for all j . We define

$$\tilde{R}_M(v, y_1, y_2) := \left(\int \frac{NM}{q} \tilde{\phi}\left(\frac{NM}{q}(v - v')\right) |R(v', y_1, y_2)|^2 dv' \right)^{1/2}.$$

Proposition 4.18. *Let*

$$\tilde{I}_{m, y_1, y_2, q_0} := \tilde{I}_{m, q_0} := \int_{v_1 \asymp 1} \left| \tilde{R}_M\left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1\right) \tilde{R}_M\left(\frac{m_1 v_1 + m_3}{-m_2}, y_2\right) R(v_1, y_1) \right| dv_1.$$

There is a choice of $q_0|q$ and $0 < M_1 \leq M \lesssim qT/N$ such that

$$S_3 \lesssim \frac{N^2 q_0}{M q^2} \sum_{|m_1| \sim M_1, |m_2|, |m_3| \sim M} \sum_{\substack{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z} \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \tilde{I}_{m, q_0} + O(T^{-100}).$$

Proof. By Proposition 4.16, we consider the terms $|m_1| \leq |m_2| \leq |m_3|$ at the cost of a factor of 6. By Proposition 4.17, we add the condition that $|m_2| \asymp |m_3|$. Expanding the sum over m_1, m_2, m_3 dyadically, we get for some $M_1 \leq M \lesssim qT/N$ and for the value of q_0 that achieves supremum.

$$S_3 \lesssim \sum_{|m_1| \sim M_1, |m_2|, |m_3| \sim M} |I_{m, q_0}| + O(T^{-100}).$$

We now consider

$$\begin{aligned}
& \int_{\substack{|v_1 m_1 + v_2 m_2 + m_3| \lesssim \frac{q}{N} \\ \frac{1}{2} \leq v_1, v_2 \leq 2}} \left| R\left(\frac{v_2}{v_1}, y_2, y_1\right) R(v_2, y_2) R\left(\frac{1}{v_1}, y_1^{-1}\right) \right| dv_1 dv_2 \\
&= \int_{\substack{|v_1 m_1 + v_2 m_2 + m_3| \lesssim \frac{q}{N} \\ \frac{1}{2} \leq v_1, v_2 \leq 2}} \left| R\left(\frac{v_2}{v_1}, y_2, y_1\right) R(v_2, y_2) R(v_1, y_1) \right| dv_1 dv_2 \\
&\ll \int_{v_1 \asymp 1} |R(v_1, y_1)| \int_{\substack{|v_2 - \frac{v_1 m_1 + m_3}{-m_2}| \lesssim \frac{q}{|m_2|N}}} \left| R\left(\frac{v_2}{v_1}, y_2, y_1\right) R(v_2, y_2) \right| dv_2 dv_1 \\
&\ll \int_{v_1 \asymp 1} |R(v_1, y_1)| \int_{\substack{|v_2 - \frac{v_1 m_1 + m_3}{-m_2}| \lesssim \frac{q}{MN}}} \left| R\left(\frac{v_2}{v_1}, y_2, y_1\right) R(v_2, y_2) \right| dv_2 dv_1
\end{aligned}$$

when $|m_2| \asymp M$. The inner integral, by Cauchy-Schwarz, is

$$\begin{aligned}
& \leq \left(\int_{\substack{|v_2 - \frac{v_1 m_1 + m_3}{-m_2}| \lesssim \frac{q}{MN}}} \left| R\left(\frac{v_2}{v_1}, y_2, y_1\right) \right|^2 dv_2 \right)^{1/2} \left(\int_{\substack{|v_2 - \frac{v_1 m_1 + m_3}{-m_2}| \lesssim \frac{q}{MN}}} |R(v_2, y_2)|^2 dv_2 \right)^{1/2} \\
&\ll \frac{q}{MN} \tilde{R}_M\left(\frac{v_1 m_1 + m_3}{-m_2 v_1}, y_2, y_1\right) \tilde{R}_M\left(\frac{v_1 m_1 + m_3}{-m_2}, y_2\right)
\end{aligned}$$

where in the last step, we used $v_1 \asymp 1$. Thus, for $|m_2| \sim M$,

$$|I_{m, q_0}| \lesssim \frac{N^3 q_0}{q^3} \frac{q}{NM} \sum_{\substack{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z} \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \tilde{I}_{m, q_0}.$$

The proposition follows from this claim. \square

To apply Hölder's inequality, we need to find bounds on the second and fourth moments of $R(v, y_1, y_2)$.

Lemma 4.19 (Second and fourth moments of R). *Let $\mathcal{S} = \{(t_j, \chi_j)\}$, such that χ_j is a character mod q , and the t 's are contained in an interval of length T , and are T^ϵ -separated for the same character. Then uniformly in $y_2 \in \mathbb{Z}/q\mathbb{Z}$,*

$$\sum_{y_1 \in (\mathbb{Z}/q\mathbb{Z})} \int_{v \asymp 1} |R(v, y_1, y_2)|^2 dv \ll_\epsilon \phi(q) |\mathcal{S}|,$$

and

$$\sum_{y_1 \in (\mathbb{Z}/q\mathbb{Z})} \int_{v \asymp 1} |R(v, y_1, y_2)|^4 dv \lesssim \phi(q) E(\mathcal{S}).$$

Proof. For the second moment, we have

$$|R(v, y_1, y_2)|^2 = \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} \chi_1 \bar{\chi}_2(y_1) \bar{\chi}_1 \chi_2(y_2) v^{i(t_1 - t_2)}.$$

By the orthogonality of characters,

$$\sum_{y_1 \in (\mathbb{Z}/q\mathbb{Z})} |R(v, y_1, y_2)|^2 = \phi(q) \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} \delta_{\chi_1 \chi_2} \bar{\chi}_1 \chi_2(y_2) v^{i(t_1 - t_2)} = \phi(q) \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} \delta_{\chi_1 \chi_2} \mathbb{I}_{(y_2, q)=1} v^{i(t_1 - t_2)},$$

so it is enough to consider the second moment of $R(v, y, 1)$ (and y_2 is coprime to q). Let ψ be a bump function supported on $v \asymp 1$ and equals 1 on the domain of integration in the lemma. Then,

$$\sum_{y \in (\mathbb{Z}/q\mathbb{Z})^\times} \int_{v \asymp 1} |R(v, y)|^2 dv \leq \sum_{y \in (\mathbb{Z}/q\mathbb{Z})^\times} \int \psi(v) |R(v, y)|^2 dv$$

$$\begin{aligned}
&= \phi(q) \int \psi(v) \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ \chi_1 = \chi_2}} v^{i(t_1 - t_2)} dv \\
&= \phi(q) \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ \chi_1 = \chi_2}} \int \psi(v) v^{i(t_1 - t_2)} dv.
\end{aligned}$$

In the sum, the terms $t_1 = t_2$ contribute $O(|\mathcal{S}|)$. If $t_1 \neq t_2$, then $|t_1 - t_2| \geq T^\epsilon$. The integral in this case is $O_\epsilon(T^{-100})$ and is negligible.

Similarly for the fourth moment, it is enough to consider $R(v, y)$. We have

$$|R(v, y)|^4 = \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S}}} \chi_1 \chi_2 \bar{\chi}_3 \bar{\chi}_4(y) v^{i(t_1 + t_2 - t_3 - t_4)}.$$

So again by the orthogonality of characters,

$$\sum_{y \in (\mathbb{Z}/q\mathbb{Z})^\times} \int_{v \asymp 1} |R(v, y)|^4 dv = \phi(q) \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \\ \chi_1 \chi_2 = \chi_3 \chi_4}} \int_{v \asymp 1} v^{i(t_1 + t_2 - t_3 - t_4)} dv.$$

Similar to the previous proof, we can introduce the bump function ψ for the integral, and restrict the summation to the terms $|t_1 + t_2 - t_3 - t_4| \leq T^\epsilon$ with an error of $O_\epsilon(T^{-100})$. The remaining terms in the summation contribute $O(E(\mathcal{S}))$. \square

Lemma 4.20. *Let $E(\mathcal{S}) = \#\{(t_1, \chi_1), (t_2, \chi_2), (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} : |t_1 + t_2 - t_3 - t_4| \leq 1, \chi_1 \chi_2 = \chi_3 \chi_4\}$. Then*

$$\sum_{y_1 \in (\mathbb{Z}/q\mathbb{Z})^\times} \int_{v \asymp 1} |\tilde{R}_M(v, y_1, y_2)|^4 dv \lesssim \phi(q) E(\mathcal{S}).$$

Proof. It is enough to show the case where $y_2 = 1$. We apply Cauchy-Schwarz to

$$\begin{aligned}
\int_{v \asymp 1} |\tilde{R}_M(v, y)|^4 dv &\lesssim \int_{v \asymp 1} \left(\int_{|u-v| \lesssim q/NM} \frac{NM}{q} |R(u, y)|^2 du \right)^2 dv \\
&\stackrel{\text{CS}}{\lesssim} \frac{NM}{q} \int_{v \asymp 1} \int_{|u-v| \lesssim q/NM} |R(u, y)|^4 du dv \\
&\lesssim \int_{u \asymp 1} |R(u, y)|^4 du.
\end{aligned}$$

Lemma 4.19 completes the proof. \square

Proof of Proposition 4.15. We exchange the summation to get

$$\begin{aligned}
&\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \tilde{I}_{m, q_0} \\
&= \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \tilde{I}_{m, q_0} \\
&= \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} |R(v_1, y_1)| \sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M\left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1\right) \tilde{R}_M\left(\frac{m_1 v_1 + m_3}{-m_2}, y_2\right) \right| dv_1 \\
&\stackrel{\text{CS}}{\leq} \left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} |R(v_1, y_1)| dv_1 \right)^{1/2} \\
&\quad \left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left(\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M\left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1\right) \tilde{R}_M\left(\frac{m_1 v_1 + m_3}{-m_2}, y_2\right) \right|^2 dv_1 \right)^{1/2} \right)^{1/2}.
\end{aligned}$$

The second moment of R (and only considering non-zero contributions from $\gcd(q, y_1) = \gcd(q, y_2) = 1$) gives

$$\left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} |R(v_1, y_1)| dv_1 \right)^{1/2} \lesssim (\phi(q)^2 |\mathcal{S}|)^{1/2} \ll \phi(q) |\mathcal{S}|^{1/2}.$$

We apply repeated Cauchy-Schwarz in the second term to get

$$\begin{aligned} & \left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left(\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1 \right) \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2}, y_2 \right) \right| dv_1 \right)^2 \right)^{1/2} \\ & \stackrel{\text{CS}}{\leq} \left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left[\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1 \right) \right|^2 \right] \right. \\ & \quad \left. \left[\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2}, y_2 \right) \right|^2 \right] dv_1 \right)^{1/2} \\ & \stackrel{\text{CS}}{\leq} \left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left[\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1 \right) \right|^2 \right]^2 dv_1 \right)^{1/4} \\ & \quad \left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left[\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2}, y_2 \right) \right|^2 \right]^2 dv_1 \right)^{1/4} \end{aligned}$$

We focus on one term, the computation of the second term is similar.

$$\begin{aligned} & \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left[\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1 \right) \right|^2 \right]^2 dv_1 \\ & \stackrel{\text{CS}}{\leq} \frac{M_1 M^2}{q_0} \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1 \right) \right|^4 dv_1 \end{aligned}$$

For any choice m_1, m_2, m_3 , we can make the change of variables $u = (m_1 v_1 + m_3)/(-m_2 v_1)$ with a Jacobian factor of $O(1)$, and the domain of integration is still $u \asymp 1$, so

$$\begin{aligned} & \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1 \right) \right|^4 dv_1 \\ & \ll \frac{M_1 M^2}{q_0} \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{u \asymp 1} \left| \tilde{R}_M(u, y_2, y_1) \right|^4 du \\ & \lesssim \frac{M_1 M^2}{q_0} \phi(q)^2 E(\mathcal{S}). \end{aligned}$$

Similarly,

$$\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left[\sum_{\substack{|m_1| \sim M_1, |m_2|, |m_3| \sim M \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2}, y_2 \right) \right|^2 \right]^2 dv_1 \lesssim \frac{M_1^2 M^4}{q_0^2} \phi(q)^2 E(\mathcal{S}).$$

Therefore, we have

$$S_3 \lesssim \frac{N^2 q_0}{M q^2} \phi(q) |\mathcal{S}|^{1/2} \left(\frac{M_1^2 M^4}{q_0^2} \phi(q)^2 E(\mathcal{S}) \right)^{1/2} \ll \frac{N^2 q_0}{M q^2} \phi(q)^2 |\mathcal{S}|^{1/2} \frac{M_1 M^2}{q_0} E(\mathcal{S})^{1/2} \lesssim \left(\frac{\phi(q)}{q} \right)^2 (qT)^2 |\mathcal{S}|^{1/2} E(\mathcal{S})^{1/2},$$

where we applied $M_1 \leq M \lesssim qT/N$ in the last step. \square

4.6 Refinement of S_3 bound

Proposition 4.21 (Refinement of S_3). *We have*

$$S_3 \lesssim \phi(q)^{7/2} T^2 |\mathcal{S}|^{3/2} + \phi(q)^3 \frac{NT}{q} |\mathcal{S}|^{1/2} E(\mathcal{S})^{1/2}.$$

The refinement of the previous bound relies on the result for summation over affine transformation by Guth and Maynard.

Lemma 4.22. *Let $M > 0$. Let $f(u) \geq 0$, supported on $u \asymp 1$, and $|\hat{f}(\xi)| \lesssim_j (|\xi|/T)^j$ for all j . Then*

$$\sup_{0 < M_1, M_2, M_3 < M} \int \left(\sum_{\substack{|m_1| \sim M_1 \\ |m_2| \sim M_2 \\ |m_3| \ll M_3}} f\left(\frac{m_1 u + m_3}{m_2}\right) \right)^2 du \lesssim M^6 \|f\|_{L_1}^2 + M^4 \|f\|_{L_2}^2.$$

This is Proposition 9.1 from [GM]. The reduction in

$$\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int_{v_1 \asymp 1} \left[\sum_{\substack{|m_1| \sim M_1, |m_2| \sim M_2 \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} \left| \tilde{R}_M \left(\frac{m_1 v_1 + m_3}{-m_2 v_1}, y_2, y_1 \right) \right|^2 \right]^2 dv_1$$

is somewhat lossy, so we aim to refine this bound in this section. In principle, the condition $y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q}$ fixes the residue class of m_3 based on m_1 and m_2 . Therefore, we would expect a factor of $1/q^2$ if we add this summation condition to Proposition 4.22.

Lemma 4.23. *Let $M > 0$. Let $f(u) \geq 0$, supported on $u \asymp 1$, and $|\hat{f}(\xi)| \lesssim_j (|\xi|/T)^j$ for all j . Then*

$$\begin{aligned} J(f) &:= \sup_{0 < M_1, M_2, M_3 < M} \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int \left(\sum_{\substack{|m_1| \sim M_1, |m_2| \sim M_2, |m_3| \ll M_3 \\ y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q_0}}} f\left(\frac{m_1 u + m_3}{m_2}, y_1, y_2\right) \right)^2 du \\ &\lesssim \frac{M^6}{q^2 q_0^2} \left(\sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int f(u, y_1, y_2) du \right)^2 + \frac{M^4}{q_0^2} \sum_{y_1, y_2 \in \mathbb{Z}/q\mathbb{Z}} \int f(u, y_1, y_2)^2 du. \end{aligned}$$

Testing proof here...

Let ψ be a smooth bump on $|x| \lesssim 1$, such that $\psi(m_3/M_3) = 1$ where $m_3 \lesssim M_3$ in the summation condition. Furthermore, let

$$\bar{y} := \bar{y}(m_1, m_2, y_1, y_2) := -m_1 y_1 - m_2 y_2,$$

so that the condition $y_1 m_1 + y_2 m_2 + m_3 \equiv 0 \pmod{q}$ becomes $m_3 = kq + \bar{y}$ for integer k . For the choice of M_1, M_2, M_3 that the supremum in the lemma is achieved, we define

$$g(u) := \sum_{m_1 \sim M_1, m_2 \sim M_2} \sum_{k \in \mathbb{Z}} \psi\left(\frac{kq + \bar{y}}{M_3}\right) f\left(\frac{m_1 u + kq + \bar{y}}{m_2}\right),$$

so that we have

$$J(f) \leq \int |g(u)|^2 du \stackrel{\text{Plancherel}}{=} \int |\hat{g}(\xi)|^2 d\xi.$$

We now compute, using the change of variables $u' = u + (kq + \bar{y})/m_1$,

$$\begin{aligned} \hat{g}(\xi) &= \int \sum_{m_1 \sim M_1, m_2 \sim M_2} \sum_{k \in \mathbb{Z}} \psi\left(\frac{kq + \bar{y}}{M_3}\right) f\left(\frac{m_1 u + kq + \bar{y}}{m_2}\right) e(-u\xi) du \\ &= \sum_{m_1 \sim M_1, m_2 \sim M_2} \int \sum_{k \in \mathbb{Z}} \psi\left(\frac{kq + \bar{y}}{M_3}\right) f\left(\frac{m_1 u + kq + \bar{y}}{m_2}\right) e(-u\xi) du \\ &= \sum_{m_1 \sim M_1, m_2 \sim M_2} \int \sum_{k \in \mathbb{Z}} \psi\left(\frac{kq + \bar{y}}{M_3}\right) f\left(\frac{m_1 u'}{m_2}\right) e(-u'\xi) e\left(\frac{kq + \bar{y}}{m_1} \xi\right) du' \end{aligned}$$

$$\begin{aligned}
&= \sum_{m_1 \sim M_1, m_2 \sim M_2} \left(\int f\left(\frac{m_1 u'}{m_2}\right) e(-u' \xi) du' \right) \left(\sum_{k \in \mathbb{Z}} \psi\left(\frac{kq + \bar{y}}{M_3}\right) e\left(\frac{kq + \bar{y}}{m_1} \xi\right) \right) \\
&= \sum_{m_1 \sim M_1, m_2 \sim M_2} \frac{m_2}{m_1} \hat{f}\left(\frac{m_2}{m_1} \xi\right) \left(\sum_{k \in \mathbb{Z}} \psi\left(\frac{kq + \bar{y}}{M_3}\right) e\left(\frac{kq + \bar{y}}{m_1} \xi\right) \right).
\end{aligned}$$

The summation in k can be rewritten through Poisson summation to get

$$\sum_{k \in \mathbb{Z}} \psi\left(\frac{kq + \bar{y}}{M_3}\right) e\left(\frac{kq + \bar{y}}{m_1} \xi\right) = \sum_{\xi'} \frac{M_3}{q} \hat{\psi}\left(M_3 \left(\frac{\xi}{m_1} - \frac{\xi'}{q}\right)\right) e\left(\frac{y \xi'}{q}\right).$$

Therefore,

$$\hat{g}(\xi) = \sum_{\substack{m_1 \sim M_1 \\ m_2 \sim M_2}} \sum_{\xi'} \frac{m_2}{m_1} \frac{M_3}{q} \hat{f}\left(\frac{m_2}{m_1} \xi\right) \hat{\psi}\left(M_3 \left(\frac{\xi}{m_1} - \frac{\xi'}{q}\right)\right) e\left(\frac{-y_1 m_1 \xi'}{q}\right) e\left(\frac{-y_2 m_2 \xi'}{q}\right).$$

By the principle of stationary phase,

$$\hat{\psi}\left(M_3 \left(\frac{\xi}{m_1} - \frac{\xi'}{q}\right)\right)$$

is negligible except when

$$\left| M_3 \left(\frac{\xi}{m_1} - \frac{\xi'}{q}\right) \right| \lesssim 1 \implies \left| \frac{q\xi}{m_1} - \xi' \right| \lesssim \frac{q}{M_3},$$

so we can truncate the summation in ξ' to be in this range.

We split

$$\int |\hat{g}(\xi)|^2 d\xi = A + B + C,$$

where

$$\begin{aligned}
A &:= \int_{|\xi| \leq T^\delta \frac{M_1}{M_3}} |\hat{g}(\xi)|^2 d\xi \\
B &:= \int_{T^\delta \frac{M_1}{M_3} \leq |\xi| \leq T^2} |\hat{g}(\xi)|^2 d\xi \\
C &:= \int_{T^2 \leq |\xi|} |\hat{g}(\xi)|^2 d\xi
\end{aligned}$$

C is negligible based on rapid decay in $\hat{f}(\xi m_2/m_1)$.

4.7 Energy bound

Here we provide the generalization for the orthogonal energy bound for Guth and Maynard's result.

Proposition 4.24. *Let $(qT)^{3/4} \leq N \leq (qT)$. Then*

$$E(\mathcal{S}) \lesssim |\mathcal{S}| N^{4-4\sigma} + |\mathcal{S}|^{21/8} T^{1/4} N^{1-2\sigma} + |\mathcal{S}|^3 N^{1-\sigma}.$$

The idea for bounding energy is similar; if $\chi_1 \chi_2 = \chi_3 \chi_4$ and $|t_1 + t_2 - t_3 - t_4|$ is small, we should expect $|D_N(t_1 + t_2 - t_3, \chi_1 \chi_2 \bar{\chi}_3)| \approx |D_N(t_4, \chi_4)| > N^\sigma$.

Lemma 4.25.

$$D_N(t, \chi) \lesssim \int_{|u-t| \leq 1} |D_N(u, \chi)| du + O(T^{-100}),$$

uniformly in χ .

Proof. (GM)

$$D_N(t, \chi) = \sum_n \omega\left(\frac{n}{N}\right) b_n n^{it\psi} \left(\frac{\log n}{2\pi}\right)$$

For other characters, we can just redefine $b'_n = b_n \chi(n)$. □

Lemma 4.26. *We have*

$$E(\mathcal{S}) \lesssim N^{-2\sigma} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^3.$$

Proof. We have

$$E(\mathcal{S}) = \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \\ |t_1 + t_2 - t_3 - t_4| \leq 1 \\ \chi_1 \chi_2 = \chi_3 \chi_4}} 1 \leq N^{-2\sigma} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \\ |t_1 + t_2 - t_3 - t_4| \leq 1 \\ \chi_1 \chi_2 = \chi_3 \chi_4}} |D_N(t_4, \chi_4)|^2.$$

Now we apply the previous lemma and Cauchy-Schwarz to get

$$|D_N(t_4, \chi_4)|^2 \lesssim \int_{|u - t_4| \leq 1} |D_N(u, \chi_4)|^2 du \lesssim \int_{|u - t_1 - t_2 + t_3| \leq 1} |D_N(u, \chi_1 \chi_2 \bar{\chi}_3)|^2 du,$$

Since χ_1, χ_2, χ_3 fixes χ_4 , and the t 's within the same character are T^ϵ separated, there is $O(1)$ possible pairs of (t_4, χ_4) for each choice of $(t_1, \chi_1), (t_2, \chi_2), (t_3, \chi_3)$, so

$$\begin{aligned} E(\mathcal{S}) &\lesssim N^{-2\sigma} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \\ |t_1 + t_2 - t_3 - t_4| \leq 1 \\ \chi_1 \chi_2 = \chi_3 \chi_4}} \int_{|u - t_1 - t_2 + t_3| \leq 1} |D_N(u, \chi_1 \chi_2 \bar{\chi}_3)|^2 du \\ &\lesssim N^{-2\sigma} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \int_{|u - t_1 - t_2 + t_3| \leq 1} |D_N(u, \chi_1 \chi_2 \bar{\chi}_3)|^2 du \\ &= N^{-2\sigma} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2), \\ (t_3, \chi_3) \in \mathcal{S}}} \int_{|u| \leq 1} |D_N(t_1 + t_2 - t_3 + u, \chi_1 \chi_2 \bar{\chi}_3)|^2 du \\ &= N^{-2\sigma} \sum_{n_1, n_2} b_{n_1} \bar{b}_{n_2} \omega\left(\frac{n_1}{N}\right) \omega\left(\frac{n_2}{N}\right) \int_{|u| \leq 1} \left(\frac{n_1}{n_1}\right)^{iu} R\left(\frac{n_1}{n_2}, n_1, n_2\right)^2 R\left(\frac{n_2}{n_1}, n_2, n_1\right) du \\ &\lesssim N^{-2\sigma} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right)^2 R\left(\frac{n_2}{n_1}, n_2, n_1\right) \right| \\ &\lesssim N^{-2\sigma} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^3. \end{aligned}$$

□

Lemma 4.27. *We have*

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^2 \lesssim |S|N^2 + |S|^2N + |S|^{5/4}(qT)^{1/2}N.$$

Proof. From the definition of R ,

$$\begin{aligned} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^2 &= \sum_{n_1, n_2 \sim N} \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} \chi_1(n_1) \bar{\chi}_1(n_2) \left(\frac{n_1}{n_2}\right)^{it_1} \bar{\chi}_2(n_1) \chi_2(n_2) \left(\frac{n_1}{n_2}\right)^{-it_2} \\ &= \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} \left| \sum_{n \sim N} \chi_1(n_1) \bar{\chi}_2(n_1) n^{i(t_1 - t_2)} \right|. \end{aligned}$$

A direct application of Heath Brown's Theorem 3.2 gives

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^2 \lesssim |\mathcal{S}|N^2 + |\mathcal{S}|^2N + |\mathcal{S}|^{5/4}(qT)^{1/2}N.$$

□

The trivial bound for $R \leq |\mathcal{S}|$ gives

$$\begin{aligned} E(\mathcal{S}) &\lesssim N^{-2\sigma} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^3 \\ &\lesssim |\mathcal{S}|N^{-2\sigma} \sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^2 \\ &\lesssim |\mathcal{S}|^2N^{2-2\sigma} + |\mathcal{S}|^3N^{1-2\sigma} + |\mathcal{S}|^{9/4}(qT)^{1/2}N^{1-2\sigma}. \end{aligned}$$

The arguments beyond will be adaptations from GM. These involve the refinement of the energy bound through the use of Cauchy-Schwarz

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^3 \leq \left(\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^2 \right)^{1/2} \left(\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^4 \right)^{1/2}.$$

Lemma 4.28. *We have*

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^4 \lesssim E(\mathcal{S})N^2 + |\mathcal{S}|^4N + E(\mathcal{S})^{3/4}|\mathcal{S}|(qT)^{1/2}N.$$

Proof. Let

$$U_B = \{(u, \chi) : u \in \mathbb{Z}, \chi \text{ character modulus } q, \#\{((t_1, \chi_1), (t_2, \chi_2)) \in \mathcal{S} : [t_1 - t_2] = u, \chi_1 \bar{\chi}_2 = \chi\} \sim B\}.$$

We split the sum in R as

$$\begin{aligned} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^4 &= \left| \sum_{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}} \chi_1 \bar{\chi}_2(n_1) \bar{\chi}_1 \chi_2(n_2) \left(\frac{n_1}{n_2}\right)^{i(t_1 - t_2)} \right|^2 \\ &= \left| \sum_{j=0}^{\lfloor \log_2 |\mathcal{S}| \rfloor} \sum_{(u, \chi) \in U_{2^j}} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ [t_1 - t_2] = u, \\ \chi_1 \bar{\chi}_2 = \chi}} \chi_1 \bar{\chi}_2(n_1) \bar{\chi}_1 \chi_2(n_2) \left(\frac{n_1}{n_2}\right)^{i(t_1 - t_2)} \right|^2 \\ &\lesssim_{\text{CS}} \sum_{j=0}^{\lfloor \log_2 |\mathcal{S}| \rfloor} \left| \sum_{(u, \chi) \in U_{2^j}} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ [t_1 - t_2] = u, \\ \chi_1 \bar{\chi}_2 = \chi}} \chi(n_1) \bar{\chi}(n_2) \left(\frac{n_1}{n_2}\right)^{i(t_1 - t_2)} \right|^2. \end{aligned}$$

Therefore,

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^4 \lesssim \sup_{j \leq \lfloor \log_2 |\mathcal{S}| \rfloor} \sum_{n_1, n_2 \sim N} \left| \sum_{(u, \chi) \in U_{2^j}} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ [t_1 - t_2] = u, \\ \chi_1 \bar{\chi}_2 = \chi}} \chi(n_1) \bar{\chi}(n_2) \left(\frac{n_1}{n_2}\right)^{i(t_1 - t_2)} \right|^2.$$

For the value of j that achieves supremum,

$$\sum_{n_1, n_2 \sim N} \left| \sum_{(u, \chi) \in U_{2^j}} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ [t_1 - t_2] = u, \\ \chi_1 \bar{\chi}_2 = \chi}} \chi(n_1) \bar{\chi}(n_2) \left(\frac{n_1}{n_2}\right)^{i(t_1 - t_2)} \right|^2$$

$$\begin{aligned}
&\leq \sum_{n_1, n_2 \sim N} \sum_{\substack{(u_\alpha, \chi_\alpha), \\ (u_\beta, \chi_\beta) \in U_{2j}}} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ \lfloor t_1 - t_2 \rfloor = u_\alpha, \\ \chi_1 \bar{\chi}_2 = \chi_\alpha}} \sum_{\substack{(t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \\ \lfloor t_3 - t_4 \rfloor = u_\beta, \\ \chi_3 \bar{\chi}_4 = \chi_\beta}} \chi_\alpha \bar{\chi}_\beta(n_1) \bar{\chi}_\alpha \chi_\beta(n_2) \left(\frac{n_1}{n_2}\right)^{i(t_1 - t_2 - t_3 + t_4)} \\
&= \sum_{\substack{(u_\alpha, \chi_\alpha), \\ (u_\beta, \chi_\beta) \in U_{2j}}} \sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ \lfloor t_1 - t_2 \rfloor = u_\alpha, \\ \chi_1 \bar{\chi}_2 = \chi_\alpha}} \sum_{\substack{(t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \\ \lfloor t_3 - t_4 \rfloor = u_\beta, \\ \chi_3 \bar{\chi}_4 = \chi_\beta}} \left| \sum_{n \sim N} \chi_\alpha \bar{\chi}_\beta(n) n^{i(t_1 - t_2 - t_3 + t_4)} \right|^2 \\
&\leq \sum_{\substack{(u_\alpha, \chi_\alpha), \\ (u_\beta, \chi_\beta) \in U_{2j}}} \left(\sum_{\substack{(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S} \\ \lfloor t_1 - t_2 \rfloor = u_\alpha, \\ \chi_1 \bar{\chi}_2 = \chi_\alpha}} 1 \right) \left(\sum_{\substack{(t_3, \chi_3), (t_4, \chi_4) \in \mathcal{S} \\ \lfloor t_3 - t_4 \rfloor = u_\beta, \\ \chi_3 \bar{\chi}_4 = \chi_\beta}} 1 \right) \sup_{|s| \leq 1} \left| \sum_{n \sim N} \chi_\alpha \bar{\chi}_\beta(n) n^{i(u_\alpha - u_\beta + s)} \right|^2 \\
&\lesssim 2^{2j} \sum_{\substack{(u_\alpha, \chi_\alpha), \\ (u_\beta, \chi_\beta) \in U_{2j}}} \left(\int_{|s| \leq 1} \left| \sum_{n \sim N} \chi_\alpha \bar{\chi}_\beta(n) n^{i(u_\alpha - u_\beta + s)} \right| ds \right)^2 \\
&\stackrel{\text{CS}}{\lesssim} 2^{2j} \sum_{\substack{(u_\alpha, \chi_\alpha), \\ (u_\beta, \chi_\beta) \in U_{2j}}} \int_{|s| \leq 1} \left| \sum_{n \sim N} \chi_\alpha \bar{\chi}_\beta(n) n^{i(u_\alpha - u_\beta + s)} \right|^2 ds
\end{aligned}$$

by Lemma 4.25. After swapping the order of summation and integration, for each fixed s , we can use Heath-Brown's theorem 3.2 to bound

$$\sum_{\substack{(u_\alpha, \chi_\alpha), \\ (u_\beta, \chi_\beta) \in U_{2j}}} \left| \sum_{n \sim N} \chi_\alpha \bar{\chi}_\beta(n) n^{i(u_\alpha - u_\beta + s)} \right|^2 \lesssim |U_{2j}| N^2 + |U_{2j}|^2 N + |U_{2j}|^{5/4} (qT)^{1/2} N.$$

Therefore,

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^4 \lesssim 2^{2j} (|U_{2j}| N^2 + |U_{2j}|^2 N + |U_{2j}|^{5/4} (qT)^{1/2} N).$$

Recall U_B contains (u, χ) that have is represented $\sim B$ times in $(\lfloor t_1 - t_2 \rfloor, \chi_1 \bar{\chi}_2)$ for $(t_1, \chi_1), (t_2, \chi_2) \in \mathcal{S}$. Therefore,

$$B|U_B| \ll |\mathcal{S}|^2.$$

Moreover, each tuple $((t_1, \chi_1), (t_2, \chi_2), (t_3, \chi_3), (t_4, \chi_4))$ satisfying $(\lfloor t_1 - t_2 \rfloor, \chi_1 \bar{\chi}_2) = (\lfloor t_3 - t_4 \rfloor, \chi_3 \bar{\chi}_4)$ also satisfies the condition for energy

$$\chi_1 \bar{\chi}_2 = \chi_3 \bar{\chi}_4, |t_1 - t_2 + t_3 - t_4| \lesssim 1.$$

Therefore,

$$B^2|U_B| \ll E(\mathcal{S}).$$

For $B^2|U_B|^{5/4}$, we can bound this by

$$B^2|U_B|^{5/4} = (B^{3/2} U_B^{3/4})(B^{1/2} U_B^{1/2}) \ll E(\mathcal{S})^{3/4} |\mathcal{S}|.$$

So we have

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^4 \lesssim E(\mathcal{S}) N^2 + |\mathcal{S}|^4 N + E(\mathcal{S})^{3/4} |\mathcal{S}| (qT)^{1/2} N.$$

□

We split the sum in $\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^3$ according to the GCD of n_1 and n_2 . Let d be this GCD, and noticing that when $q|d$, we have $R(n_1/n_2, n_1, n_2) = 0$,

$$\sum_{n_1, n_2 \sim N} \left| R\left(\frac{n_1}{n_2}, n_1, n_2\right) \right|^3 \leq \sum_{d \leq D} \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2) = 1}} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3 + \sum_{d > D} \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2) = 1}} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3,$$

where D is a parameter to be decided.

We first take care of the large GCD terms using CS. By our two bounds on the second and fourth moments,

$$\begin{aligned} \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2)=1}} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3 &\leq \sum_{n'_1, n'_2 \sim (N/d)} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3 \\ &\lesssim \left(|\mathcal{S}| \left(\frac{N}{d} \right)^2 + |\mathcal{S}|^2 \frac{N}{d} + |\mathcal{S}|^{5/4} (qT)^{1/2} \frac{N}{d} \right)^{1/2} \\ &\quad \left(E(\mathcal{S}) \left(\frac{N}{d} \right)^2 + |\mathcal{S}|^4 \frac{N}{d} + E(\mathcal{S})^{3/4} |\mathcal{S}| (qT)^{1/2} \frac{N}{d} \right)^{1/2}. \end{aligned}$$

Summing over $d > D$ (and using Cauchy-Schwarz to move the summation into the square root) gives the following result.

Proposition 4.29. *We have*

$$\begin{aligned} \sum_{d > D} \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2)=1}} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3 &\lesssim \left(|\mathcal{S}| \frac{N^2}{D} + |\mathcal{S}|^2 N + |\mathcal{S}|^{5/4} (qT)^{1/2} N \right)^{1/2} \\ &\quad \left(E(\mathcal{S}) \frac{N^2}{D} + |\mathcal{S}|^4 N + E(\mathcal{S})^{3/4} |\mathcal{S}| (qT)^{1/2} N \right)^{1/2}. \end{aligned}$$

When d is small, we expect fractions n_1/n_2 for $n_1, n_2 \sim N/d$ to be well-distributed across $\asymp 1$, so we would like to estimate the summation in terms of an integral.

Lemma 4.30. *Let n_1, n_2 be coprime to q . We have for $v \asymp 1$,*

$$|R(v, n_1, n_2)| \lesssim T \int_{|s| \lesssim 1/T} |R(v+s)| ds.$$

Proof. Recall

$$R(v, n_1, n_2) = \sum_j \chi_j(n_1) \chi_j(n_2) v^{i(t_j)},$$

so it suffices to prove the relation for any

$$f(v) = \sum_j c_j v^{i(t_j)},$$

uniformly for $|c_j| \leq 1$. Let ψ be a smooth bump that equals 1 on $[0, 1]$, then

$$f(v) = \sum_j c_j v^{i(t_j)} = \sum_j c_j e(t_j \log v / (2\pi)) \psi(t_j/T) = \sum_j c_j e\left(\frac{t_j \log v}{2\pi}\right) \int \hat{\psi}(\xi) e\left(\frac{t_j \xi}{T}\right) d\xi$$

The right hand side equals

$$\int \sum_j c_j \hat{\psi}(\xi) e\left(t_j \left(\frac{\xi}{T} + \frac{\log v}{2\pi}\right)\right) d\xi.$$

By the rapid decay in $\hat{\psi}$, we can truncate the integral to the range $|\xi| \lesssim 1$ at a cost of $O(T^{-100})$, and use the trivial bound $\hat{\psi}(\xi) \ll 1$. Therefore,

$$|f(v)| \ll \int_{|\xi| \lesssim 1} \left| \sum_j c_j e\left(t_j \left(\frac{\xi}{T} + \frac{\log v}{2\pi}\right)\right) \right| d\xi + O(T^{-100}).$$

We now make the change of variables

$$\log s = \log v + \frac{2\pi\xi}{T},$$

so this gives a Jacobian factor of T , and

$$|f(v)| \ll T \int_{|s-v| \lesssim 1/T} \left| \sum_j c_j e\left(\frac{t_j s}{2\pi}\right) \right| ds + O(T^{-100})$$

which gives the bound in the lemma upon making a second change of variables $v' = s - v$. \square

Returning to the small GCD terms, we have for a not divisible by q ,

$$\begin{aligned} \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2)=1 \\ n'_1/n'_2 \cong a \pmod q}} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3 &\stackrel{\text{H\"older}}{\ll} T \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2)=1 \\ n'_1/n'_2 \cong a \pmod q}} \int_{|s - \frac{n'_1}{n'_2}| \lesssim 1/T} |R(s, a)|^3 ds \\ &\leq T \int_{s \asymp 1} |R(s, a)|^3 \left(\sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2)=1 \\ n'_1/n'_2 \cong a \pmod q \\ |s - \frac{n'_1}{n'_2}| \lesssim 1/T}} 1 \right) ds. \end{aligned}$$

We now consider for two distinct pairs $(n_1, n_2), (n_3, n_4)$ satisfying $\gcd(n_1, n_2) = \gcd(n_3, n_4) = 1, n_1/n_2 \cong n_3/n_4 \cong a$,

$$\left| \frac{n_1}{n_2} - \frac{n_3}{n_4} \right| = \left| \frac{n_1 n_4 - n_2 n_3}{n_2 n_4} \right| \geq \frac{qd^2}{N^2}.$$

Therefore, the sum is $O(1 + N^2/(qd^2T))$. So we have

$$\begin{aligned} \sum_{d \leq D} \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2)=1}} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3 &= \sum_{a \pmod q} \sum_{d \leq D} \sum_{\substack{n'_1, n'_2 \sim (N/d) \\ (n'_1, n'_2)=1 \\ n'_1/n'_2 \cong a \pmod q}} \left| R\left(\frac{n'_1}{n'_2}, n'_1, n'_2\right) \right|^3 \\ &\ll T \sum_{d \leq D} \left(1 + \frac{N^2}{qd^2T}\right) \sum_{a \pmod q} \int_{s \asymp 1} |R(s, a)|^3 ds \\ &\stackrel{\text{CS}}{\ll} T \left(D + \frac{N^2}{qT}\right) \left(\sum_{a \pmod q} \int_{s \asymp 1} |R(s, a)|^2 ds \right)^{1/2} \left(\sum_{a \pmod q} \int_{s \asymp 1} |R(s, a)|^4 ds \right)^{1/2} \\ &\lesssim (qTD + N^2) |S|^{1/2} E(S)^{1/2}. \end{aligned}$$

Picking the choice of $D = N^2/(qT)$, we have produced all analogs of the generalizations of Guth and Maynard's result in bounding energy. The remaining part is to reduce our bounds. The computations are exactly the same except replacing T with qT . Thus we have

$$E(S) \lesssim |S| N^{4-4\sigma} + |S|^{21/8} T^{1/4} N^{1-2\sigma} + |S|^3 N^{1-\sigma}.$$

4.8 Proof of main theorem

Proof. By Proposition 4.7, we have

$$|S|^3 \lesssim \frac{\phi(q)^3}{q^3} N^{6-6\sigma} + N^{3-6\sigma} (S_1 + S_2 + S_3).$$

By Proposition 4.12, S_1 is negligible. We bound S_2 by Proposition 4.13, and S_3 by Propositions 4.21 and 4.24. Therefore,

$$\begin{aligned}
|\mathcal{S}|^3 N^{6\sigma-3} &\lesssim_k \frac{\phi(q)^3}{q^3} N^3 + \frac{\phi(q)}{q} \left(|\mathcal{S}|^2 N + |\mathcal{S}|^{2-1/k} N^2 + |\mathcal{S}|^2 N^2 \left(\frac{(qT)^{1/2}}{|\mathcal{S}^{3/4}|} \right)^{1/k} \right) \\
&\quad + \phi(q)^{7/2} T^2 |\mathcal{S}|^{3/2} + \phi(q)^3 \frac{NT}{q} |\mathcal{S}|^{1/2} (|\mathcal{S}|^2 N^{2-2\sigma} + |\mathcal{S}|^3 N^{1-2\sigma} + |\mathcal{S}|^{9/4} (qT)^{1/2} N^{1-2\sigma})^{1/2} \\
&\ll \frac{\phi(q)^3}{q^3} N^3 + \frac{\phi(q)}{q} \left(|\mathcal{S}|^2 N + |\mathcal{S}|^{2-1/k} N^2 + |\mathcal{S}|^2 N^2 \left(\frac{(qT)^{1/2}}{|\mathcal{S}^{3/4}|} \right)^{1/k} \right) \\
&\quad + \phi(q)^{7/2} T^2 |\mathcal{S}|^{3/2} + \phi(q)^3 \frac{NT}{q} |\mathcal{S}|^{1/2} (|\mathcal{S}| N^{1-\sigma} + |\mathcal{S}|^{3/2} N^{1/2-\sigma}).
\end{aligned}$$

where in the last step we take $N > (qT)^{3/4}$, so that $|\mathcal{S}|^{9/4} (qT)^{1/2} N^{1-2\sigma}$ is dominated by $|\mathcal{S}|^2 N^{2-2\sigma}$.

$$\begin{aligned}
|\mathcal{S}| &\lesssim_k \frac{\phi(q)}{q} N^{2-2\sigma} + \frac{\phi(q)}{q} N^{4-6\sigma} + \left(\frac{\phi(q)}{q} N^{5-6\sigma} \right)^{k/(k+1)} + \left(\frac{\phi(q)}{q} \right)^{4k/(4k+3)} N^{4k(5-6\sigma)/(4k+3)} (qT)^{2/(4k+3)} \\
&\quad + \phi(q)^{7/3} T^{4/3} N^{2-4\sigma} + \phi(q)^2 \left(\frac{T}{q} \right)^{2/3} N^{(10-14\sigma)/3} + \phi(q)^3 \frac{T}{q} N^{9/2-7\sigma}
\end{aligned}$$
